"The contravention by a registered medical practitioner of the provisions of the Dangerous Drugs Acts and the regulations made thereon may be the subject of criminal proceedings, and any conviction resulting therefrom may be dealt with as such by the Council under the powers given them by Section 29 of the Medical Act. But" (and this, said the President, is the important point) "any contravention of the Acts or the Regulations involving an abuse of the privileges conferred thereunder upon registered medical practitioners, whether such contravention has been subject to criminal proceedings or not, will, if proved to the satisfaction of the Council, render a registered medical practitioner liable to have his name erased from the Medical Register."

I call your attention, Mr. Connor, to the terms of that warning notice, and although I know that upon the convictions which have been obtained you have already been punished, it is desirable, considering your methods of practice, that you should be put on probation for one year.

## REPORTS OF COMMITTEES AND OTHER BUSINESS.

### MONDAY, MAY 31ST.

At a meeting of the Executive Committee the official notification was made of the reappointment of the following members of the Council: Dr. Wardrop Griffith, Dr. H. L. Eason, Dr. A. F. Dixon, and Sir James Hodsdon.

The following names, erased under Section 14 of the Medical Act, 1858, were restored to the Medical Register: Thomas G. Burnett, George H. Coke, Ahmed R. W. Dina, Victor T. W. Eagles, Thomas V. Hunter, William A. McEnery, Henry G. H. Monk, Samuel K. Norris, Ernest A. Runting, Alice I. Shaw, Henry J. Villiers.

### *The Irish Free State and Medical Registration.*

The Executive Committee approved a suggestion, which had been received from the Rt. Hon. T. M. Healy, Governor-General of the Irish Free State, to the effect that a conference should take place between the representatives of the British Government and of the Irish Free State with a view to the making of permanent arrangements in the matter of medical registration.

### *Society of Apothecaries: Honours Certificate in Obstetrics.*

A communication was made recently to the Privy Council by the Society of Apothecaries as to the institution of a registrable diploma for proficiency in obstetrics, when a reply was sent that fresh legislation would be required before this could be done. The Society, having later applied to the Privy Council for guidance as to the issue of an Honours Certificate, that body referred the point to the General Medical Council, who now advised that it would be inexpedient for the Privy Council "to express beforehand an opinion on a subject which might come before them officially and perhaps judicially."

The Right Hon. Edward Hilton Young, D.S.O., D.S.C., joined the Council as Crown Nominee for five years from May 23rd, 1926.

The Finance Committee's report was laid before the Council by the Chairman and adopted unanimously.

Mr. Norman C. King was reappointed Registrar to the General Council and thanked by acclamation for his work in surmounting the difficulties created by the strike.

The session closed with a vote of thanks to the President.

FLOATING REST HOMES ON THE VOLGA.—The Russian Red Cross reports a new development of prophylactic work against tuberculosis. The Moscow Health Department is organising this year fortnightly cruises along the Volga and Kami rivers in newly-repaired well-equipped vessels. It is hoped thus to provide holidays for 2400 workers this summer.

# Reviews and Notices of Books.

## CHRONIC INFECTION OF THE JAWS.

By STANLEY COLYER, M.D., M.R.C.P., D.M.R.E., Radiologist, Mildmay Mission Hospital; late Assistant Radiologist, Royal Dental Hospital. London: H. K. Lewis and Co. 1926. Pp. 76. 10*s.* 6*d.*

THIS book consists of a short radiological and clinical survey of the subject of chronic infection of the jaws. The author has had extensive experience of the clinical practice of dentistry and of general medicine outside his specialty, so that his conclusions as to the significance of the radiological aspects of jaw infections merit respect. Of the two parts of the book, the radiological study is the more interesting. During the last few years Dr. Colyer has put forward in various publications his views on the significance of dental radiographs. He believes that certain minute changes in the appearance of the bone are indicative of infection and have thus a definite diagnostic value. He carries the interpretation of dental films much further than do many of his colleagues, and believes that when correctly examined they may yield information which could not possibly be gained by unaided clinical examination. Dr. Colyer here gives an account of the normal film-picture of the teeth and jaws, as well as of the appearances occurring in disease, and the significance which he believes may be attached to these. Quite apart from the gross apical rarefaction so often seen, he describes small areas of rarefaction which may exist in the deeper part of the bone. According to the author these small areas can be distinguished from nutrient canals by the pattern of the surrounding bone. Dr. Colyer's views have attracted considerable interest among dentists, but while the appearances described by him can frequently be seen in good dental films, there is not yet unanimity as to their significance. It seems probable that much of what Dr. Colyer has to say is correct, yet until there is independent corroboration by methods of examination other than radiography, his views must still remain hypothetical. But before we can allow of a high value being attached to this appearance as a diagnostic sign, still more before we should allow it to influence treatment, there ought to be some corroborative evidence. When apical rarefaction as seen in a film is assumed to indicate infection, the facts that such areas are absent in normal jaws, and that the soft mass of tissue which frequently comes away when the affected teeth are removed shows microscopic signs of an infective process, give independent support to this assumption. There is prima facie evidence that the current value attaching to such an appearance in a radiograph is more or less justified, though even here there are obvious pitfalls, for the radiograph does not enable us to distinguish with certainty between an abscess and a mass of innocuous epithelial cells. If it were possible to provide corresponding confirmation of the accuracy of Dr. Colyer's interpretation of the radiographic signs of infection in the jaws, their value would be greatly strengthened. It might not be easy, but it should be possible to get films taken of the jaws in a certain number of post-mortem cases with pyorrhœa. If a film revealed those changes which Dr. Colyer considers to be indicative of deep infection, then sections could be made from the jaws which would either confirm or disprove his views. It is just because we are impressed with the possible importance of Dr. Colyer's hypotheses, and because we feel that his work is so suggestive, that we consider that further investigation by other methods is demanded.

A notable feature of the book is the large number of very beautiful reproductions of films showing both normal and pathological conditions. Dr. Colyer laments the inability of the process block to reproduce the finer details seen in a good film, but these illustrations are certainly among the best we have seen. The book should be studied by every dentist and radiologist. They may not always find themselves in agreement with the author, but they can *hardly fail* to be impressed both by his evident sincerity and the thoughtful and logical sequence of his argument. If the perusal of his book leads to a more careful examination of dental films by transmitted light in a viewing box, Dr. Colyer will have written to sound purpose.

---

## DISEASES OF CHILDREN.

By H. C. CAMERON, M.D. Cantab., F.R.C.P. Lond., Physician-in-charge of Diseases of Children, Guy's Hospital. London: Humphrey Milford, Oxford University Press. 1926. Pp. 199. 5*s.*

THE object of the Oxford University handbooks is to provide a general survey of various branches of medical science. This object has been attained with striking success by Dr. Cameron in this little book, which is written with the charm and insight which his former writings have led the reader to expect from him. It is in no sense a text-book, and should not be used to replace one, but the reader will gain from it a more balanced view of the significance of the facts presented in text-books of pediatrics. The essential differences in the outlook with which the practitioner should approach the study of child and adult patients are set out in a lucid and convincing manner, and important points, such as the small part played by drugs in the treatment of infants, are brought to notice. Each chapter comprises a review of the special problems which arise in dealing with some period of development or some common group of symptoms, such as diseases of the newly-born, the various digestive disturbances, nervous unrest, catarrh, predisposition to disease, and the effect of conduct and management upon health. The chapter on diet, which includes artificial feeding of infants, is a triumph of condensation, and will greatly assist the student to assimilate the wealth of lengthy and contradictory accounts with which he will sooner or later be faced.

This book may be strongly recommended to students and to all practitioners who are concerned with the treatment of children. In particular medical men and women embarking on general practice will be wise to procure it, and will gain from it an insight which is not always obtained from hospital routine into some aspects of a most important branch of their work.

---

*Kinderheilkunde.* By Dr. R. LEDERER, Vienna. Berlin: Julius Springer. Pp. 100. $1.65.

THIS monograph forms a unit of Dr. Julius Bauer's "Konstitutions-pathologie in den medizinischen Spezialwissenschaften," and has as its object the recognition and estimation of the constitutional element in growth, development, and disease in children. Purely hereditary diseases such as hæmophilia are not discussed. The term *constitution* is used in the purely genotypic sense, referring only to factors transmitted by the germ-plasm. The first chapter is concerned with general considerations on heredity, predisposition, and their connexion with the nervous and endocrine systems. In the chapter entitled Constitution and Growth various examples of diminished growth—dwarfism, infantilism, infantile atrophy—are considered, and an attempt is made to differentiate in each case the (endogenous) hypoplastic element from the conditioned or hypotrophic element. The most speculative and controversial part of the work is found in the chapter on Constitution and Habitus; the author adopts the classification of Sigaud in preference to that of Kretschmer, and attempts the division of infants and children into his four types—respiratory, digestive, muscular, and cerebral. The morphological characteristics of these types are described at some length and illustrated by photographs. The final section on Constitution and Bodily Condition contains an analysis of the ætiological factors of some pathological conditions characteristic of childhood, particularly the chronic nutritional disorders. Special attention is given to the work of Czerny and Finkelstein on hydrolability and the exudative diathesis. Recent work on the ætiology of rickets and of spasmophilia is reviewed in a well-balanced and critical manner; the author concludes that in spite of the apparent predominance of environmental or nutritional factors in the production of these states, there is a true endogenous constitutional factor consisting of a displaced relationship between the mineral constituents of the organism.

Dr. Lederer has presented with great ability his views on an aspect of medicine which is claiming an increasing amount of attention, and this monograph will provide much that is of interest to advanced students of the subject.

### PUBLIC HEALTH LABORATORY WORK (CHEMISTRY).

Eighth edition. By HENRY R. KENWOOD, C.M.G., M.B., F.R.S. Edin., Emeritus Professor of Hygiene, University of London. London: H. K. Lewis and Co. 1925. Pp. 369. 12*s.* 6*d.*

THE chemical requirements of students of public health are adequately fulfilled by Prof. Kenwood in a volume of less than 400 pages. This in itself is an achievement. The essentials of each subject are clearly defined and the descriptions of what to do and how to do it are lucid. Certain sections are really excellent; others give the impression that the author is not greatly interested in the subjects dealt with. It is regrettable that the first few pages are among the less carefully prepared passages. It is difficult to believe, for example, that Prof. Kenwood has ever himself obtained precipitates of ammonium salts, of nitrates, or of the chlorides of sodium or potassium which he has weighed after ignition in the manner here described, or that the descriptions of the balance, the spectroscope, the polariscope, which he appears to associate with the refractometer, and the burette represent his considered view of these instruments. On the whole, however, methods of examination of water, sewage, air, foods, and disinfectants are well described. The chapter on water analysis is especially good. The methods discussed are for the most part well chosen, and the real difficulty of interpreting results is largely removed by the many examples of analyses and reports. The author justly devotes attention to the microscopy of water. The plates of objects found in water are hardly up to the standard of the text. Dibdin's microfilter is not mentioned; it is a great improvement on the Blyth's tube which is described. The following sentence from this section of the volume might well be hung up in all water laboratories: "Between an undoubtedly bad water and an undoubtedly good water there are waters regarding which no opinions ought to be advanced unless advantage is taken of a careful local inspection to detect any possible source of pollution and both a bacteriological and a chemical analysis are performed."

The chapter on sea water is marred by two inadequate and unrepresentative analyses. This is the more to be regretted as the author and F. N. Kay Menzies have done excellent work on criteria of purity of sea water. The statement that sea water does not contain phosphoric acid might be challenged. The small amount it does contain is a determining factor in the growth and decay of plankton and thus has an important bearing on fish life. Brucine is not, we hold, a trustworthy reagent for detecting nitrates in sea water.

Sewage and mud are dealt with adequately in 12 pages, whilst 47 pages are given to air. No reference is made to Dr. J. S. Owens's excellent devices for determining suspended impurities in air or to the work of the Meteorological Office Committee on atmospheric pollution, though other methods of collecting suspended matter are given.

The author writes wisely on preservatives. He points out that their use facilitates an uncleanly, slovenly treatment of food and renders it possible to preserve articles in incipient decomposition for some time with every appearance of freshness. Some reference to hydrion-concentration and the pH of Sörenson might usefully have been added to the chapter on acidimetry and alkalimetry, and a more modern treatment of these subjects might with advantage be adopted in a subsequent edition. A bibliography would be a useful adjunct.

Throughout this text-book Prof. Kenwood shows sound judgment based on ripe experience.

### DICTIONARY OF APPLIED CHEMISTRY.

Revised and enlarged edition. By Sir EDWARD THORPE, C.B., LL.D., F.R.S. London: Longmans, Green and Co. 1926. Vol. VI. Pp. 791. £3.

ON the death of Sir Edward Thorpe in February, 1925, it was found that much progress had been made with the two last volumes of this dictionary. The final revision has been carried out by Dr. H. Forster Morley, and it is hoped that the final volume, containing an index to the whole work, will be published before the end of this year. The sixth volume of this magnificent dictionary deals with subjects comprised within the letters "S. Acid" to "Tetryl." Most of the articles have been written by authoritative contributors and constitute valuable summaries of the chief branches of applied chemistry. Among the subjects of especial interest to the medical man may be mentioned salicylic acid and its derivatives, santonin, the treatment of sewage, silver compounds, soaps, the sugar in blood and its estimation. Prof. Barger contributes an interesting and fairly comprehensive article on synthetic drugs; the information relating to taste, tea, and terpenes is well up to date.

In this dictionary reliable information can be quickly collected on almost any subject connected with the science of chemistry; moreover, the liberal use of references to published work indicates the direction in which more complete study can be made.

### BIOLOGICAL MEMORY.

By EUGENIO RIGNANO, Professor in the University of Milan, &c. Translated with an Introduction by E. W. MACBRIDE, D.Sc., LL.D., F.R.S. London: Kegan Paul. 1926. Pp. 253. 10*s.* 6*d.*

Prof. Rignano makes a bold effort to account for those differences between living and non-living matter which have already led to the production of so many theories. By memory he does not indicate the power of conscious recall of past experiences, but rather the power of repeating habits that date from the previous experience of the individual or the race, and this power is the characteristic of living tissue. He elaborates a centro-epigenetic hypothesis, in terms partly physiological and partly vitalistic, which calls for a trophic nervous energy passing from nucleus to nucleus and leaving in its path a "specific accumulation" which can originate by its decomposition exactly that kind of nervous current by the action of which it was deposited.

To the physiological reader such mixed hypotheses are provoking when they are produced as satisfying solutions of the great problem. But, fortunately, the author indulges in a friendly controversy with Prof. Bottazzi, a partisan of physico-chemical theories of life—which theories may be equally provoking to those who cannot be content with the effort to explain living and non-living matter by a single conceptual system. In his reply to criticism, Prof. Rignano frankly admits ignorance of the physiological basis of the mnemonic faculty or of the property of forming "specific accumulations." His theory is, he claims, merely an attempt to group together under one system a number of facts concerning heredity and kindred subjects for which no single generalisation has yet been offered. Thus viewed, his theory comes to be ranked as legitimate hypothesis and may be compared with Darwin's ideas of pangenesis and Weismann's theory of the continuity of the germ plasm. Like those, it may be expected to arrest attention and to stimulate further attempts to understand the basis of the phenomena studied.

# THE LANCET.

*LONDON: SATURDAY, JUNE 12, 1926.*

## X RAY TREATMENT OF CANCER.

X RAYS have now been tried in the treatment of malignant disease for 25 years; some of the early beneficial results were obtained with rays of long wave and correspondingly small penetrating power, the dosage being empirical. As time went on shorter rays of greater penetration were used in the hope of reaching deeply situated organs. During the war a method of accurately estimating the quantity of X rays emitted from a tube was worked out in Germany, and a system was evolved by which dosage could be measured, not only on the skin, but in the depths. The quantity of rays which any one portion of skin would tolerate was taken as the unit, and by means of crossfire through different ports of entry doses larger than could be borne by the skin were given to tumours at a depth. Reports of the results obtained by these massive doses, brought to this country by Dr. REGINALD MORTON and others five years ago, were more than encouraging, especially those from the clinic at Erlangen under Prof. WINTZ, where administration of massive doses of penetrating rays continuously for many hours resulted in the "clinical cure" of 80 per cent. of cases of uterine carcinoma so treated—that is to say, they were still well three years or more after. The Erlangen results were, in fact, so superior to those obtained by surgical methods that, as Dr. MORTON stated in a recent letter, surgery was abandoned at this clinic for cases of malignant disease in the female. The results obtained in this clinic were, however, not reproduced by others who tried the method; many patients suffered severely from the inevitable destruction of red cells and failed to recover their hæmic equilibrium; in some cases death followed as an immediate or remote result of the severe reactions.

The original Erlangen technique proved unsuited to the majority of cases seen in this country. For this reason, both here and in Stockholm under Prof. FORSSELL, a variation of the single massive dose method was introduced and the majority of workers now divide up the large dose over several days. There are grounds for believing that tissue cells, whether normal or malignant, are more radio-sensitive during certain stages of mitosis than at others, and by dividing the dose it is hoped to catch all the malignant cells at a susceptible time. There is also the constitution of the patient to be borne in mind. As Dr. F. HERNAMAN-JOHNSON puts it,[1] radiation treatment must be attuned to the estimated power of constitutional response in the individual patient. The results so obtained have been extremely variable, and even the keenest radiologists admit disappointment and the inability to forecast the result with any feeling of confidence. The cases which they undertake, however, are almost always in extremis or at all events beyond the reach of surgery. Dr. HERNAMAN-JOHNSON writes bluntly: "To British radiologists the treatment of carcinoma of the womb is of little practical importance, for they never see it." There is no material for the comparison of the results obtained by radiologists with those of surgeons, because they do not deal with the same kind of cases. There is, we believe, sufficient evidence to show that X rays (and, of course, radium) can do a great deal in certain types of cancer; rodent ulcer almost invariably disappears with small divided doses of X rays, and of all forms of internal cancer early carcinoma of the uterus is most analogous to rodent ulcer in its clinical behaviour. Prof. WINTZ himself has claimed a large measure of success in cancer of the breast. But in general the success so far achieved is not sufficient to justify radiologists in demanding that they should treat all early cases of cancer in advance of the surgeon. The position is complicated by the tendency on the surgeon's part, should the patient recover after X rays alone, to regard the diagnosis of cancer as incorrect, more especially as cases that are treated only by radiations are rarely sectioned. Spontaneous cure of well-established malignant disease is indeed not unknown. It may be taken as beyond dispute that massive doses of X rays will cause large tumour masses to disappear, but this experience is not synonymous with the cure of the primary disease. After irradiation of the primary lesion an existing metastasis may break into a fierce activity. The same phenomenon is, however, only too well known after operative treatment of a slow growing tumour, recurrences of an extremely active type making their appearance sometimes within a few weeks. There is strong evidence to indicate that any interference with a malignant growth may change its nature, whether this interference be operative or by means of radiations. Recent papers at the German X Ray Congress at Berlin seemed to indicate that, as regards cancer of the breast, the intensive treatment with rays of great penetrating power was not only ineffective but positively harmful. On the other hand, the statistics of the clinics in which rays of moderate penetration only were used were much more satisfactory, an experience which we believe is shared by the majority of radiologists in this country. Surgeons are divided in their opinions as to the value of post-operative irradiation of breast cases, and some of them have abandoned their use in breast cases after operation. Nevertheless, there are many surgeons who insist on post-operative irradiation as early as possible, not even waiting for the healing of the wound. LEWIS JONES recognised long ago[2] that in the X ray treatment of malignant disease there is "the strange phenomenon of the profound influence exercised by the rays, with a strange insufficiency so far as final cure is concerned." Cases are known in which the apparent disappearance of a local breast cancer after X ray treatment has reduced the breast to a condition in which operation could be undertaken, when section has still shown the presence of carcinomatous cells.

In some ways the position has not altered much since Mr. CECIL ROWNTREE wrote 14 years ago[3]: "Many surgeons consider X rays to be useless in the treatment of inoperable cancer. Some regard them as actually harmful when applied in frequently repeated doses; a few, a very few, have had experience of cases in which apparent cure has followed their application." And even in the present stage of knowledge there cannot be many radiologists who would press for sole responsibility in the treatment of early cancer cases on the strength of the admittedly good results of Prof. WINTZ in dealing with cancer of the cervix uteri. There are, however, a number of cases in which, though the cancer is early, operation is contra-indicated owing to some general cause. If these cases were submitted to irradiation on the lines suggested by Dr. MORTON and the results collected and published, the objects which he has in mind would be attained without contravening the principle, firmly established in this country, that early excision is the correct treatment for early cancer. Dr. PODKAMINSKY, in a much-criticised letter, quotes LEVY-DORN'S gibe that the proved successes of radiotherapy are two—epilation and castration. It is in fact the only agency we know which has a definite effect on malignant growth of all kinds.

## THE DENTAL BOARD'S BUDGET.

THE Dental Board of the United Kingdom has the disposal each year of a large sum of money, for the Board prescribes a fee of £5 for the annual retention of any name on the Dentists Register, apart from names which appear there by right acquired prior to the Dentists Act of 1921. This Act laid down that any moneys received by the Board after paying the expenses of administration should be devoted to dental education and research or other public purposes connected with the profession of dentistry at the discretion of the Board. Strong pressure has been put upon the Board to reduce the amount of this annual levy upon its registrants, many of whom are not well off, and Mr. F. D. ACLAND, Chairman of the Board, devoted the larger part of his address at the opening of its tenth session on May 25th to a consideration of the Board's budget. Should the present retention fee be adhered to, the income of the Board will be above £50,000 for several years to come. The general expenses of the Board amount to about £12,000, and there is a possibility, happily not yet realised, of incurring heavy legal expenses in taking important cases to the courts. A reserve of £11,000 odd is earmarked for the teaching schools and, with the surplus of the present year, should meet their legitimate requirements for some years to come. A grant of £5000 a year is made to research, an amount which Mr. ACLAND would like to increase, impressed, as he is, with the approach of recent work to the edge of knowledge fundamental to prophylaxis. Dental health education is costing the Board about £4000 a year; post-graduate lectures account for another £1500, and students' bursaries already granted will amount to £21,000 a year when in full swing. Setting all these items of expenditure against the income derived from the payment of 9288 retention fees, "we could," said Mr. ACLAND, "with a little squeezing and a little going slow, and a little luck, and a little willingness to dip into reserve, get along fairly well with an annual retention fee of £4 instead of £5."

If this were all, the question of Dental Board finance would be simple, but there is much doing in the immediate future. As soon as dental benefit is provided under the National Health Insurance scheme —and the provision is imminent—the amount available from approved society funds for this benefit will be not less than £2,000,000 a year, over 10 millions of insured persons becoming entitled to demand it. The extra demand for dental service which will result must be met by a sufficient supply of dentists. Before the war an annual entry of rather over 250 licentiates maintained a slightly increasing Register of about 5000 practising dentists. Now the Register is over 14,000 and the number entering the schools last year was only 345. "I do not believe," said Mr. ACLAND, "that a Register of 14,000 will be permanently maintained unless 700 students a year enter the schools, and this number is just over double the present actual entry." He went on to speak quite frankly of the fact that in a few years' time the absolute monopoly of dental practice now enjoyed by dentists may be difficult to defend and that in consequence a strong demand may arise for a lower qualification. Dentists now have the tightest monopoly enjoyed by any profession, but no one complains of it, for the fees charged cannot be represented to be in excess of the value of the work done. But what if alongside an increasing demand for dental services there should be a considerable fall in the numbers on the Dentists Register? Hitherto the Board has done all in its power to make easy the path of the entrant to the dental profession. It has assisted 147 students who would not otherwise have entered the dental schools, the average annual cost of each grant being £122. Last March there was keen competition for bursaries and an attempt was made to help as many as possible with the money available; 27 grants were then awarded at an average annual cost of £106. Continuing on that basis 75 students a year would be assisted. If, as has been suggested, the basis of awards is changed and prize bursaries of £80 a year for four years are offered to 66 students a year, this much could be done, but not more with an annual retention fee of £4. Knowing that there ought to be a much larger dental entry, shall the Board, by reducing the present fee, put it out of its power to increase the number to whom help can be granted? Taking a long view, Mr. ACLAND concluded that it would be unwise in the general interests of the dental profession and of the public to reduce the fee permanently at the present time. The tax should, however, be as easy as is consonant with enlightened administration, and the first motion, after the Chairman concluded his address, was to ask the Finance Committee to consider and report what reduction, if any, would be necessary in the special expenditure of the Board on education and research to permit the retention fee to be reduced to £4 or, alternatively, to £3 in 1927.

## SPA TREATMENT.

OFFICIAL courtesy has made it possible for a representative of THE LANCET to make a detailed investigation of the position to-day of ten spas in Western Germany which were formerly visited by foreigners, and on p. 1164 is given a brief account of his findings. Speaking generally, he found the methods of treatment employed in German spas substantially the same as those of British spas. Bath treatments, it is true, are given on a vastly larger scale in Germany, but since one patient can only use one bath at a time, the individual derives little benefit from this circumstance. Whilst our representative found numerous English-speaking German doctors and hotel employees, few of the bath attendants spoke any English; consequently, unless the patient speaks at least a little German, difficulties might arise. Accessibility must be considered; the six-and-a-half hour crossing from Harwich to the Hook, followed by a considerable train journey, may be a serious deterrent to patients in indifferent health. On the other side is to be set the intangible but very real advantage of complete change of scene in many chronic maladies which require baths. Complete removal from the toils of business life and domestic worry, the breaking of a vicious circle of bad habits, these aids to effective treatment are more readily achieved in novel surroundings, and it is no doubt on this account that spa treatment has become international. The gain is mutual, for visits from other countries to home spas should be set against the visits of our own people to foreign health resorts.

The German spa industry has fallen on hard times. Deprived of its former rich Russian clientèle and of practically all British and French visitors, efforts are being made to resume relations with other nations. Most of the spas are State concerns, and the State is spending money freely in keeping them up to date. The cost of treatment is a serious consideration for most patients nowadays, and it is doubtful whether a cure in a German spa can be obtained as cheaply by British people as in a home spa if the additional cost of travelling is considered, especially if the patient cannot travel alone. The value of the mark now corresponds very closely to that of the shilling, and the cost of treatments in shillings and marks appears to be much the same. The charges of first-class hotels in Germany are lower certainly than in this country, the daily rate being from 12 marks upwards. The cost of the baths may be a trifle lower, although a mud or peat bath costs 7 or 8 marks—*7s. 6d.* in this country. Medical fees in the German spas are, on the whole, lower than in this country, a first consultation for 15 marks, followed by subsequent consultations at 7½ marks, being a fair average. The Germans would appear to have more faith in the specific action of their mineral waters than some of our own spa doctors. Water-drinking and bathing never occupy a secondary place, consequently accessory treatments are much less employed, and there is not the same tendency to try to speed up the cure. A month to six weeks is the shortest course prescribed. The patient will have four baths a week and see the doctor on two of the blank days.

Nauheim treatment is given in many of the spas, though probably nowhere so well as in Nauheim itself. In this line of treatment Great Britain cannot compete until some source of thermal carbonated saline is tapped—which seems unlikely enough. Artificially aerated baths can, of course, be given anywhere, but it should not be overlooked that this is only one, and by no means the most important, of the hydrotherapeutic measures which are so beneficial in certain disorders of the cardiovascular system. Ems treatment has not been attempted seriously in this country, though most German spas have their inhalatoria and their gargling and spraying rooms. Our winter climate is so unkind to patients with chest complaints that it is doubtful whether it would ever be successful except in the summer months. But with these two exceptions our representative did not find any treatments given at the ten German spas which cannot be obtained equally well at home. A "cure tax" is levied in all German spas, and whatever may be said for or against it in principle it undoubtedly enables the spa management to provide music and keep up gardens in a style beyond the means of most British spas. Orchestras are, however, now so expensive that no Austrian spas are providing music this year, and, unless conditions improve, it seems possible that Germany may have to follow suit. There is a large supply of pamphlets in English about German spas. These would be of much more use if they specified clearly in what treatments and for what complaints the particular spa specialises. The claims are so wide as to be of little use to the practitioner seeking guidance as to choice of spa. It usually results in the practitioner sending his patient to the spa at which he happens to know a doctor. Nor is great harm done thereby as the principles of balneological treatment are the same everywhere.

◆

# THE LISTER INSTITUTE OF PREVENTIVE MEDICINE.

AT the annual general meeting held on June 9th of the Lister Institute, it was announced that Prof. C. J. Martin has been granted three months sick leave, and that Prof. A. Harden has been appointed deputy director during his absence. Dr. Muriel Robertson has resumed duty after absence on sick leave. Dr. G. F. Petrie has been appointed bacteriologist in charge of the serum department in succession to Dr. MacConkey, who has retired after holding this post for 20 years. The Governing Body records its high appreciation of the services rendered to the Institute by Dr. MacConkey during this period. The Medical Research Council have continued to render support to the work of the Institute. Besides furnishing the salaries of the staff of the National Collection of Type Cultures, the Council has provided two whole-time workers in the department of bacteriology, Dr. H. M. Woodcock and Mr. P. Bruce White, one in the department of biochemistry, Dr. S. S. Zilva, and six in the department of experimental pathology, Prof. Korenchevsky, Miss E. M. Hume, Miss K. L. Soames, Miss M. Carr, Miss Henderson Smith, and *Miss Leigh Clare.* Dr. T. *Lumsden's* work on cancer is carried on under a grant from the British Empire Cancer Campaign. Accommodation for all these workers and the expenses of their researches are provided by the Institute. The various investigations in progress are summarised in the annual report. Prof. J. C. G. Ledingham is continuing his studies of the viruses of variola, vaccinia, and avian molluscum. It is hoped that the experimental findings may throw valuable light on the irregularities met with in converting small-pox to the vaccinial form—a transformation which involves increased virulence of the original virus for the rabbit and a diminished virulence for man. Dr. J. A. Arkwright has continued his observations on the variation of bacteria in vitro. Dr. H. L. Schütze is studying plague vaccine of various types. The work of this department includes also investigations into types of gonococcus, the pasteurisation of milk and bovine tuberculosis, scarlet fever and streptococci, hydrogen peroxide and bacterial growth, and other studies covering a wide field. The department of biochemistry is no less active. Prof. Harden is conducting experiments on the nature of the substance, contained in yeast and many vegetable extracts, which has a powerful stimulating effect on the growth of yeast and is considered by many workers to belong to the class of vitamins. Using lemon juice as the source of this material it has been possible to concentrate it considerably and to separate it from the antiscorbutic vitamin. The process of alcoholic fermentation, the synthesis of fat and carbohydrate by vegetable organisms, and the transformation of sugars are also being studied. In the department of experimental pathology the acid-base equilibria of blood has been investigated by micro-methods. Much time and attention has been devoted to the development of trustworthy methods for assay of the fat-soluble vitamins, here differentiated as the anti-ophthalmic vitamin A and the antirachitic vitamin D. It is now clear that vitamin D is not less necessary for growth than vitamin A. Some of the biological tests to be used in an international comparison of biological and colorimetric methods of titrating vitamin A are being carried out by Miss Soames assisted by Miss Leigh Clare in this department. The mechanism by which ultra-violet light acts upon the skin in animals is being studied by Miss Hume, Miss Henderson Smith, and Dr. N. S. Lucas. The recent publication from the laboratories of the Institute on foot-and-mouth disease, by Dr. Arkwright and his co-workers, has already been noticed in our columns, and this is true of many of the 47 publications issued from the Institute in the period under review. The income for the year was £50,000, mainly made up of £11,000 from interest on investments and £35,000 from sales of sera and vaccines and fees for investigations performed. There is an excess of income over expenditure of some £14,000, the expenditure being accounted for in detail as rent, salaries (£18,000), laboratory expenses (£4000), purchase, housing and feeding of animals, library and workshop expenses and repairs, renewals, and alterations. The stationery and printing accounts are modest and the travelling expenses singularly so.

# Annotations.

"Ne quid nimis."

## SIR FREDERICK MOTT.

As we go to press we learn with deep regret the death of Sir Frederick Mott. On May 26th he was taken ill in the train while travelling to Birmingham to visit the laboratory at Hollymoor Asylum. At the General Hospital, Birmingham, he was found to be suffering from widespread cerebral thrombosis from which he never rallied and to which he succumbed on June 8th. For some months he had slight premonitory signs, but characteristically he carried on with his duties as Honorary Director of Research on Mental Diseases to the Corporation and University of Birmingham without regard to his physical health. His death at the age of 72 will be deplored by all our profession, and especially will he be missed by those engaged in psychiatry and its large modern developments, for it was hoped that for many years he would still be in a position to stimulate and guide them.

His distinguished career and his scientific attainments give him a unique place in the medical world, but it is his genial personality, his wide range of interests, his humanity and enthusiasm, which will make his loss so deeply felt and regretted by all who have had the privilege of coming into personal contact with him. His reputation is international. He was well known abroad as one of the great scientists of England, who kept close touch with workers of all nations, and was the personal friend of many of them. His researches are quoted constantly in foreign literature, and he maintained to the last a keen interest in the work of other nations. In his own specialty of nervous and mental disease he was both clinician and research worker, equally at home by the bedside and in the laboratory, and in both displaying his sound sense and judgment of values. For many years he has inspired research workers, and his energy and enthusiasm has laid the foundation of a school of research into the physical factors underlying mental disease from which many valuable contributions have emanated. He was the first worker in England to confirm the discovery of the spirochæte of syphilis in the brains of general paralytics, and his labours and those of his collaborators have produced a great body of evidence concerning the changes found in the nervous and endocrine systems in dementia præcox. His researches were mainly concerned with morbid anatomy, but he also realised that this line of work had its limitations; he fostered biochemical and physiological inquiry in his laboratory, seeing clearly that the next step on the path towards the understanding of mental disease processes was likely to be taken in that direction. While his own work was chiefly directed towards investigating physical factors, he took a keen interest in the psychological and philosophical problems involved in mental and nervous disease, and the whole problem of the interrelation of body and mind. Some of his most recent writings have been on this subject. He always cared deeply for music, wrote on the brain and the voice in speech and song, and was recently still working on the comparative anatomy of the vocal apparatus and its cerebral representation; and he believed in music as a valuable aid in the treatment of mental disorder. It was largely owing to his energy and force of character that the scheme of his friend, Dr. Maudsley, for the establishment of a hospital for the treatment of early cases of mental and functional nervous disease came to fruition, and the Maudsley Hospital, to which the central laboratory of the L.C.C. mental hospitals was transferred, owes him a debt at least as great as to its founder, for his unfailing interest in all its activities.

A correspondent writes: "All those who have had the privilege of knowing him will always think of him with the deepest respect and affection. He took a human and personal interest in those who worked with him, was always accessible and ready to help, willing to hear any problem, and to bring his great range of knowledge to bear on its solution, thus inspiring everyone with his own enthusiasm. He was a great man as well as a great scientist, and a beloved teacher to the school he did so much to found."

The fuller obituary notice will appear next week.

## THE IMPORTATION OF FOOT-AND-MOUTH DISEASE.

The origin in this country of fresh outbreaks of foot-and-mouth disease apparently unconnected with previous cases of the disease has long been a standing puzzle to administrators and farmers in spite of all the labours of that great investigator Sir Stewart Stockman, whose obituary notice appears on another page. A recent outbreak in Scotland, where the disease is comparatively very rare, has led to the detection of carcasses of pigs imported from Rotterdam with lesions of foot-and-mouth disease on them. These carcasses had already been received at three different places in Great Britain, two of them bacon factories, and had reached this country in two or more different ships. As a result of this disclosure the Ministry of Agriculture has issued an order prohibiting the importation of carcasses from continental Europe after June 3rd. The term carcasses includes meat, hides, bones, horns, hoofs, blood, and offals, except in the case of fully cured meat and hides. There was a strong presumption that the carcasses discovered were actually infective, and it is stated that direct experimental evidence was obtained that this was the case. The exact path by which the infection passed from the carcasses to living animals is not quite clear, but the explanation would be very simple if portions of the meat were given to pigs to eat and the disease then spread to other animals; failing this route other hypotheses could readily be framed. Though it has often been suspected that infected fodder may introduce the disease, the evidence for or against this possibility has in the past been so conflicting that it cannot be said to have been generally accepted as a very probable or frequent source of danger, and other explanations have been as freely suggested with no more certain support from ascertained facts. The chief argument against the transmission by such means is the rapidity with which infected material has often been found to become inactive at ordinary temperatures, especially if exposed to sunlight and drying. The German Commission of 1898 could not show that the virus would survive drying at all. French workers, however, found that under very special circumstances virus may be dried and remain active for a long time. Recently it has been determined that the conditions for the viability of the virus in dried discharges or blood are much more common than has been supposed. Among other facts bearing on the problem which have come to light in recent years are the infectivity of the blood and all the organs during the initial fever and during the first day or two of illness, and the rapid disappearance of the virus from the skin, blood, and other parts of the body after the earliest stages of the disease. Nevertheless, the epithelium, discharges, and blood retain their activity at cool temperatures for a long time if removed from the animal during the height of the infective period. It follows, therefore, that blood, tissues, and especially local vesicles in carcasses of animals killed early in an attack are likely to be a source of danger for some time after slaughter, especially if frozen or chilled. It has been known for many years that experimental feeding of animals with recently infected fodder may serve to induce the disease, and the infection of pigs by feeding with contaminated offal has been strongly suspected in other countries. From the consumer's point of view, apart from the probably very slight risk of infecting human beings through diseased meat, the question arises whether efficient inspection of carcasses would not obviate the need for a complete embargo. The fact that the carcass may be infective without characteristic lesions or after removal of obviously diseased portions, and that blood and offals may also be infective largely disposes of this plea. The onus of proving freedom from infection must rest with those who would favour the continued importation of carcasses from neighbouring countries where foot-and-mouth disease is rife.

## THE BOTELHO REACTION FOR CANCER.

EVER since the Wassermann reaction gained recognition as a satisfactory aid to the diagnosis of syphilis the search for a method of serum diagnosis in cancer has been progressing. The latest claimant for notice is the "Reaction of Botelho," which forms the subject of a recent monograph by Beatrix Tedesco-Pollack[1] based on work done at the Hôtel-Dieu in Paris. The author of the reaction, whose identity is not made clear in the monograph, is, as our Paris correspondent has indicated, a pupil of Dr. Hartmann's, who, while making observations on the glycogen content of serum noted that certain cancerous sera gave a precipitate with the iodine-potassium-iodide solution used in the detection of this substance, a phenomenon which failed to occur with normal serum. The admixture of such a solution with the serum forms the basis of the reaction, which has been much refined by its originator and Mlle. Tedesco-Pollack. The test must be performed in an acid medium, and for this purpose either citric or nitric acid may be used; the latter is recommended. For the nitric-acid form of the reaction the following solutions are necessary:—

| | | |
|---|---|---|
| 1. | Nitric acid (pure at 36° Beaumé) .. .. | 1 c.cm. |
| | Physiological saline (7·5 per cent.) .. .. | 100 c.cm. |
| 2. | Metallic iodine, twice sublimated .. .. | 1 g. |
| | Iodide of potassium .. .. .. .. | 2 g. |
| | Distilled water .. .. .. .. | 210 c.cm. |

In its simplest form the reaction is performed as follows:—

Into a test-tube about 12 × 1 cm. are placed 3 c.cm. of the nitric-acid reagent and 0·5 c.cm. of the serum to be tested. Mix and then add the iodine-iodide reagent as follows. First pour in 0·5 c.cm. of the reagent and shake gently until the precipitate disappears. Wait 30 seconds. Add a further 0·5 c.cm. of the same reagent and again shake gently until the precipitate which reforms has either disappeared or sunk to the bottom of the tube. Lastly add a further 0·3 c.cm. of the reagent, again shaking gently and finally closing the mouth of the tube with the thumb and inverting it. A positive reaction is indicated by the persistence of a precipitate sufficiently dense to obscure the view of the filaments of an electric lamp when viewed through the test-tube.

Botelho, while working on his test, came to the conclusion that a high concentration of albumin in the serum tended to obscure a positive reaction, while vice versa sera low in albumin tended to give false positives. Mlle. Tedesco-Pollack has devised a technique for determining the albumin content of the serum by the refractometer and then by dilution with saline, bringing it to the optimum for the reaction. For details of this the original monograph should be consulted. Using this improved technique this worker claims to have been able to obtain positive results in over 90 per cent. of 145 cases of cancer, while 55 controls gave negative results in 85·5 per cent. of cases. These results are comparable with those achieved by their devisers with many other tests for cancer produced in the past, a fact of which Mlle. Tedesco-Pollack is well aware and which she duly notes in her extensive review of the subject. Since her monograph was compiled a further series of 200 cases has been examined at the Paris Radium Institute where Dr. Jacques Lavedan found a positive Botelho reaction in 85 per cent. of cases of breast cancer, but in only 35 per cent. of cases where the cancer was localised in the skin. He also found the reaction positive in certain cases of typhoid, diabetes, tuberculosis, and syphilis. The reaction accordingly, while it has some theoretical interest, does not as yet afford much practical help in diagnosis.

## A MEDICAL VISIT TO BIARRITZ.

WITH a view to familiarising British medical men with the advantages of Biarritz as a health resort a party of London practitioners was entertained by Dr. Plantier, during the Whitsuntide recess, at the large hydropathic institution which he directs. The "Hélianthe," as it is called, although situated only a few minutes' walk from the centre of the town, has an uninterrupted view of the Bay of Biscay and the Western Pyrenees in front and abuts on open country behind. The climate of Biarritz is pleasant all the year round; there is little difference in the reading of the thermometer in the sun and in the shade, and no sudden chill at sundown. A stay at an institution of this kind is indicated for those who need sea air together with an equable climate; it is beneficial for that class of patients, so well known to practitioners, who are suffering from the stress and strain of modern life, or who need a complete rest after a serious illness or operation. Sufferers from dyspepsia, obesity, gout, and diabetes are well looked after, as a feature of the establishment is the supply of special diet to all who require it. Care is taken that all directions prescribed by the patient's own physician are carefully carried out. The "Hélianthe" has its own private path to the sea beach where there is safe bathing, while for those who prefer to bathe in the hotel a large swimming pool is provided. Turkish and light baths are available, as well as all the modern contrivances of physiotherapy. The high insolation prevailing at Biarritz makes it an ideal centre for heliotherapy; Dr. Plantier has provided spacious terraces for sun bathers, who are enabled to take their cure under the pleasantest conditions. The staff of medical assistants, nurses, masseuses, and electro-therapists, as well as the hotel personnel proper, is all chosen personally by Dr. Plantier and affords a happy example of team-work. The percentage charge for service robs the day of departure of its sting for less hardened travellers.

## OLEOTHORAX.

OLEOTHORAX is attracting some interest abroad. Dr. M. G. Kuss gives an account[1] of this new method of treatment introduced by Dr. A. Bernou[2] in 1922, which he has found useful in pneumothorax, whether artificial or spontaneous, and in empyema. Briefly, the method consists in filling the pleural cavity, partially or completely, with a non-irritant oil which has an antiseptic action on the pleural membrane. Several varieties of bland oil have been used for the purpose. Liquid paraffin has the advantage of being easily sterilised and of high viscosity, whilst it undergoes no change in the pleural sac and is only slowly absorbed. Gomenol, an essential oil distilled from a species of myrtle and popular in France, has been added to the paraffin in view of its bactericidal value and also relative non-toxicity. As much as 400–600 c.cm. of oil can be injected into the pleura at one time, but in the case of a healthy pleura without effusion an initial injection of 10–20 c.cm. is considered advisable. The oil should be warmed before use. It can apparently be safely used as a means of replacement instead of air, and Dr. Kuss gives exact details of its employment for this purpose. The effect of bland oils upon the growth of *B. tuberculosis* has recently been worked out by Ross[3] and Tulloch in Dundee, and from their work it may be assumed that oil, injected into the pleural cavity, will have an inhibitory effect on the tubercle bacillus. This, however, is only one small side of the question. Bacteria, especially tubercle bacilli, are not necessarily free in the pleural fluid or pus; the majority of the organisms lie beneath the pleural endothelium in the lymphatics of the subpleural connective tissue layer, and it is impossible to decide.

on our present information, whether or not the presence of oil on the free surface of the pleural endothelium affects bacteria in the subpleural layers. There is also the question whether oil, lying in the pleural sac for many weeks, will act as a foreign body and induce the production of adhesions. Finally, there is the question of the absorption of the oil. The small amount of work which has been done on the subject so far seems to indicate that the oil is absorbed, although slowly. The effect of such absorption has still to be worked out.

## TRAUMA AND MALIGNANT GROWTHS.

IN the clinical history of sarcomatous growths of bone there is often a story of a local injury having occurred at a comparatively short time before the first appearance of the disease. Speculation has been rife as to whether the injury has any causal connexion with the growth of the tumour and pathologists in particular have thrown doubt on this relationship, finding it difficult to explain how simple trauma can set in motion processes which ultimately lead to the formation of sarcomata. It has been asserted in standard text-books of surgery that it is a coincidence and nothing more when a growth arises in a limb which has been subjected to injury, or that the growth pre-existed and was lighted up by the injury into increased activity. Sixteen years ago Dr. W. B. Coley, whose experience in sarcoma of the long bones is unrivalled, brought forward a number of facts in order to demonstrate his belief that the growth of sarcoma of bone often did depend in some way upon antecedent injury. In a recent communication to the Southern Surgical Association of the United States, which is to appear in the *International Journal of Surgery*, Dr. Coley reaffirmed this opinion and brought forward additional cases which go far to establish trauma as the exciting cause of the formation of sarcoma. Of 360 cases observed by himself he obtained a history of previous injury in no less than 181, a percentage of over 50. The case-histories are given in detail and some of them are striking. For instance, a child of 5 fell against a corner of a table. She suffered from severe abdominal symptoms, for which a laparotomy was done on the third day. At this operation the surgeon found a hæmatoma in the transverse mesocolon. He let out the blood-clot and tied a bleeding vessel. The child recovered. Four weeks later symptoms recurred and in the abdomen was found a large tumour at the site of the injury. One month later exploratory laparotomy showed the abdominal cavity to be filled with sarcomatous nodules, apparently secondary to a large primary growth in the region originally contused. Dr. Coley cites cases where, following injury to a bone, a hæmatoma has appeared and been operated upon, where the X ray has shown no sign of malignant disease, and yet a few weeks later a growth has appeared. He points out that it is far commoner to get a history of injury in periosteal sarcoma than in central sarcoma and he endeavours to explain this difference. He cites the analogy of osteomyelitis, where it is well known that an injury to a bone may cause a latent infection to light up. Experiments with staphylococci thrown into the circulation in animals have demonstrated that infection of the joints and bones occurs almost with certainty when a local injury is produced afterwards. Dr. Coley himself believes that the association of injury with sarcoma is definite evidence in favour of sarcoma being due to external infective agents, the injury producing a local loss of resistance to infection. He suggests that local injury of the tissues gives rise to the formation of the specific factor required by the hypothesis of Gye and Barnard. Whatever may be the truth of the origin of sarcoma, no one can read these cases reported by Dr. Coley and remain unconvinced that trauma can play some part in its genesis.

## STATUS LYMPHATICUS.

THE diagnosis of status lymphaticus in cases of sudden death without obvious or adequate cause is perhaps not so popular as it was a few years ago, but is still sufficiently common to merit attention. Indeed, under the auspices of the Medical Research Council and the Pathological Society of Great Britain and Ireland a committee has been set up to inquire into the matter. A high proportion of these cases has followed the administration of brief anæsthetics for minor operations and it is difficult to avoid the conclusion that in some of them, at least, the diagnosis is open to doubt. Autopsy experiences in large cities lead to the conviction that a large number of the perfectly healthy children who are killed every year in street accidents exhibit hyperplasia of the lymphoid tissue throughout the body; yet the lorry or the motor-bus is so clearly the cause of death that status lymphaticus is never referred to. It is only when similar children succumb during operations for tonsillectomy or the like that a more recondite explanation is sought for. Apart from these instances, however, there are others when death follows upon a trivial injury or occurs with tragic suddenness from no apparent cause. Such a case is reported by Dr. James Miller in the *Canadian Medical Association Journal* for May. It is that of a young undergraduate, 19 years of age, who during a strenuous game of tennis on a bitterly cold day staggered a couple of paces and then collapsed, dying a few moments later. At the autopsy which was performed four hours later a condition of general lymphoid hyperplasia was found, with a persistent thymus weighing 14 g. The thyroid gland showed a mild condition of colloid goitre, and the brain was large and œdematous. Beyond some evidence of quiescent tuberculosis in the lung apices nothing else of any moment was discovered, and the diagnosis of death from status lymphaticus was given. On the face of it the diagnosis would seem fully justified, but on closer examination of the case certain omissions appear which diminish its value as a contribution to this important subject. It is strongly held by some authorities that a fine fatty degeneration of the cardiac muscle is the chief lesion in this condition and the determining cause of death, but no reference to the myocardium is made in this case. Again, E. Glynn has shown that sudden death may occur in the earliest stages of meningitis when the disease is practically not demonstrable except by bacteriological methods. Apparently, however, Dr. Miller made no bacteriological examination, and this is to be the more regretted since the patient had been in poor health for some time before his death. It is also noteworthy that a fortnight before he had had an unexplained fainting attack. The suspicion remains, therefore, that Dr. Miller's case is not one of true status lymphaticus, but is rather an example of cardiac failure from myocardial degeneration, if, indeed, an active infection can be ruled out. The question as to the existence of status lymphaticus is one of great importance. It is likely enough that the conception would not have fallen into the disrepute which it undoubtedly has had it not been, if not exploited, at least used as a cloak to cover ignorance. Only after the most thorough and systematic exclusion of other possibilities is it justifiable to make the diagnosis of status lymphaticus, and Dr. Miller's note will have fulfilled a useful purpose if it serves to point this moral.

## COMPLIMENTARY DINNER TO SIR STCLAIR THOMSON.

IT was a happy thought of the Section of Laryngology of the Royal Society of Medicine to give a complimentary dinner to the President of the Society, that leading laryngologist and sympathetic figure-head, Sir StClair Thomson. Upwards of 200 friends and professional colleagues, with their wives and guests of either sex, sat down to dinner on Friday last, June 4th, at the Hotel Victoria to display their attachment to Sir StClair Thomson and recognition of his merits as man of science and official. The guests included the President of the Royal College of Physicians of London, two Vice-Presidents of the Royal College of Surgeons of England, Sir StClair Thomson's successor in the presidential chair of the Royal Society of Medicine, and many well-known physicians and surgeons. The proceedings were throughout of a very cordial nature. Dr. W. H. Kelson, President of the Section of Laryngology, made a happy speech from the chair in which he outlined briefly the guest's career and his high professional and social qualities, to which Sir StClair Thomson replied in a very happy manner. His anecdotes were good, his Shakespearean quotations were apt, and his acknowledgment of the compliment paid to him was a model of what such difficult speeches should be, both in sincerity and in the turning of phrases. His last quotation was Byron's celebrated exhortation, "On with the Dance," and there being no more speaking beyond the vote of thanks to the chair, the company took the floor. A material memento of the occasion was provided by the presentation to Sir StClair Thomson of a massive silver drinking-cup.

## OBJECTS RESEMBLING SPIROCHÆTES.

SINCE the discovery of the spirochæte as an agent of disease, and coincident with the extension of its importance in medicine from a very restricted to a wider and expanding field, mistakes have over and over again occurred from the technical difficulties in studying these organisms and in their demonstration and culture. In staining, many of them—most notoriously that of syphilis—have so little affinity for dyes that their tinctorial demonstration in tissues is impossible, and it is only by silver impregnation methods that they can be shown. These methods are uncertain in action, and apt to be complicated by the occurrence of precipitates which obscure observation and may lead into errors, whilst the affinity of certain tissue elements for silver salts may result in the bringing into prominence of fibrils which resemble the spirochæte and have from time to time been erroneously mistaken for them. Culture, the main line of examination pursued by the bacteriologist, is in regard to these organisms laborious and uncertain, so that it is at present rather a hazardous method of research than a helpful procedure in clinical diagnosis. In these straits recourse is widely made to the dark background methods of illumination, which enable the organisms to be seen in their living state and their movements to be studied. This method, which is perhaps the most satisfactory in our existing armamentarium, also has its limitations and its pitfalls. Chief amongst the former is the fact that it can only be applied to materials relatively free of particles other than the organisms. Thus, whilst useful in studying the juice of a chancre or the organisms found in a culture, it cannot be applied to a tissue emulsion. Amongst the latter difficulties is the fact that certain bodies may occur in experiments which, whilst resembling spirochætes, are not these. If blood cells be kept for some time in culture, or other fluid media, long trailing streamers of the envelope material of the red cells appear in connexion with them, and, floating out in the fluid under the influence of molecular impacts, take on movements not unsuggestive of autonomy. During the war a pathologist observing such "streamers" became convinced that in them he had discovered a microbic cause for trench fever and many other conditions as well. In a recent paper[1] Noguchi, who has contributed so much to our knowledge of spirochætes, points out that in impure cultures of these organisms the detached flagella of motile contaminating bacilli may very closely resemble spirochætes, and records that for some time he himself mistook these structures for aberrant forms of *Treponema macrodentium*, with which he happened to be working. Further, many spirochætes develop in cultures well-marked terminal flagella which, becoming separated from the organism, may closely resemble a minute spirochæte. It is well that these sources of error should be recorded, as, since such able and accustomed workers are liable to be misled by them, they are worthy of being given every publicity so that others, who with less experience are working in the fields in which they are met, may be forewarned.

## BIRD DROPPINGS.

IN his recent annual report as medical officer of health for the City of London Dr. W. J. Howarth drew attention to the nuisance caused by the increasing number of pigeons, especially in Leadenhall Market, where their excreta contaminate the stalls above which they congregate. Although there is no actual evidence of danger to health there are considerable possibilities of contamination of food, and Dr. Howarth considers that legal powers to reduce the number of pigeons may be desirable. Those engaged in safeguarding the purity of water-supplies have long recognised that the excreta of certain birds may be a cause of contamination of the water-supply and must be kept in mind as a possible explanation of anomalous bacteriological findings. The excreta of pigeons and gulls, and probably many other birds, contain both colon bacilli and streptococci in large numbers and of types which cannot be differentiated from similar organisms derived from human or animal sources. Sir Alexander Houston has pointed out[2] that while the diving gulls (e.g., guillemots) feeding on clean sea water in non-polluted areas do not harbour the colon bacillus in their intestines, the common gulls seasonally forsaking the sea and feeding on all sorts of garbage inland contain this type of organism in their fæcal discharges in enormous numbers. The droppings of gulls frequenting the West Middlesex Waterworks were found to contain at least 1,000,000 typical colon bacilli per gramme. Taking 10 g. of droppings per day it will be appreciated that the resulting *B. coli* contamination of the water-supply, even if it has no immediate epidemiological importance, may interfere seriously with the correct interpretation of bacteriological water tests and obscure the chemical tests by introducing considerable quantities of albuminoid ammonia. These difficulties are most likely to be met with in upland surface water-supplies. Happily there is little evidence of the presence of pathogenic bacilli in the excreta of birds. The only strains known to have been associated with human disease are certain members of the Salmonella group, of which *B. psittacosis* is the most important. This organism has been isolated from parrots and the disease has spread to man. In April, 1892, an extensive outbreak occurred in Paris with 42 known cases involving 14 deaths. Serologically this strain has now been identified with *B. aertrycke*, the bacillus most commonly associated with outbreaks of human food poisoning. Salmonella strains have also been isolated from pigeons and other birds. With our present knowledge it may be said that while contamination from bird droppings must be regarded as a nuisance there is no scientific evidence associating such contamination with disease causation.

THE second Victor Horsley Memorial Lecture will be given in the Council Room of the British Medical Association House, Tavistock-square, on Friday, July 9th, at 5 P.M., by Mr. Wilfred Trotter, who has taken as his subject the Insulation of the Nervous System. The chair will be taken by Sir John Bland-Sutton, F.R.C.S. Admission is free to practitioners and students on presentation of a visiting card.

A PLAZA THEATRE BED.—The staff of the Plaza Theatre have endowed a bed in Charing Cross Hospital, and last week a tablet commemorating the event was unveiled by Miss Dorothy Gish. The nucleus of the cost was provided by gratuities for the employees placed by visitors in a box at the theatre.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXXVI.—THE TREATMENT OF ANÆMIA.

### I. Pernicious Anæmia.*

Before undertaking the treatment of a case of pernicious anæmia it is essential to realise what that condition means. Various views obtain regarding the pathology of the disease, but the outstanding fact is that the patient has an insufficient supply of hæmoglobin for his respiratory needs. His tissues lack oxygen. Moreover, the bone-marrow is poisoned and the hæmoglobin which it produces is contained in red corpuscles unduly large, so that the central portion is handicapped as a respiratory agent. The heart is enfeebled. The gastric juice lacks HCl. The kidneys are damaged. The nervous system may be impaired and the tissues offer a very poor resistance and little reaction to infection. A remarkable feature of the disease is the incidence of remissions and relapses. The remissions are often attributed to the last medicine given. It is a curious fact that nearly all cases first come under observation with a red cell count round about 1·2 millions per c.mm. and 30 per cent. of hæmoglobin.

*Rest in Bed.*—Obviously, a patient who has less than one-third of his normal complement of hæmoglobin—and that badly arranged—should be kept in bed. The duration of the stay in bed depends upon progress. In a first attack events move more quickly than in relapses. Death may occur in a few weeks. More likely a remission takes place and in this case every endeavour should be made to persuade the patient to remain in bed till the hæmoglobin percentage reaches 60. He will never again get so good a chance of recovery. In a relapse 60 per cent. may be too high an aim. If hope of its attainment be too long deferred it may be well to allow the patient to get up when the hæmoglobin reading reaches 40. This may become the average reading in patients leading useful if not very active lives.

A patient confined to bed should get as much fresh air and sunlight as may be available.

*Removal of Septic Foci.*—Whether infection acts by poisoning the red corpuscles (excessive hæmolysis) or by poisoning the bone-marrow (deficient hæmogenesis) or merely by lowering the general health, it should be dealt with. Teeth affected by caries or associated with pyorrhœa should be treated as early as possible. The nasal cavities may require attention and any infection of the genital tract should be treated. In initial attacks and in severe relapses one may attempt to alter the intestinal flora by a milk diet for 10 or 14 days, giving an enema daily. β naphthol, gr. x., in cachets may also be given.

*Diet.*—For ten days, or longer if jaundice persists, milk and light farinaceous food only are allowed.

There is sometimes a degree of gastric irritation which makes feeding very difficult. In these cases peptonised milk, whey, or dilute whisky may be tried. After ten days, in the absence of jaundice or gastric derangement, chicken, fish, and custard may be added. Later, ordinary food may be allowed, but the amount of red meat should always be restricted. A little light wine may be given with the midday meal as a stimulant to appetite. An egg-flip containing two teaspoonfuls of whisky or brandy is a useful " extra."

Meat extracts and soups have a certain use as mild stimulants in acute cases, but they are rich in extractives and for routine use they are better avoided. In my post-mortem experience I have never seen a case of pernicious anæmia with healthy kidneys.

*Gastric Symptoms.*—The diminution or absence of HCl is an indication for its administration. Small doses of the dilute acid may be given after meals. Shaw (*Quart. Jour. Med.*, 1924, p. 319) has suggested the "continuous" administration of HCl by giving it in lemonade, to be sipped during an hour after taking food. Some cases improve, but it is noteworthy that large or even moderate doses are not well borne. In cases of severe vomiting alkaline sedatives are of service. The citrate of bismuth and ammonia, milk of magnesia, and similar preparations are useful. Gastric lavage is too severe a measure for patients desperately ill and morphia is not well borne.

*Arsenic.*—In spite of diversity of view concerning the pathology of the disease and the numerous alleged remedies which have been boomed from time to time, arsenic continues to be the therapeutic mainstay of the overwhelming majority of medical practitioners.

There is a tendency to reduce the large doses which were formerly given. I seldom give more than 5 minims of Fowler's solution thrice daily and find that in this form arsenic is well tolerated ; if it be desired to combine arsenic with HCl or iron the liq. arsenici hydrochlor. should be used. It is always well to interrupt arsenical treatment at intervals. After a month it should be dropped for a week. The tongue should be inspected frequently for any sign of irritation or the silvery appearance that indicates that the limit of tolerance is approaching. The onset of sickness or diarrhœa indicates that arsenic should be stopped. Dropsy and œdema may be caused by arsenic and their onset should not be accepted without question as features of the disease. Arsenic also appears capable at times of causing or maintaining a febrile condition.

When even small doses of arsenic set up gastric irritation *intramuscular* or *intravenous* administration may be tried. Fowler's solution (3 to 5 minims well diluted) may be injected into a muscle with the usual precautions to avoid nerves and tendinous attachments. The gluteus maximus one inch below the iliac crest towards the outer side is a useful site. Obviously a patient will not hanker after frequent repetition of this procedure and the physician has to be content with one injection daily. A similar disadvantage is associated with intravenous injection. This method may be preferred to the intramuscular route when the veins are reasonably prominent, but the technical difficulties may be considerable in a very bloodless patient. Three or four minims of liq. sodii arsenatis in 5 to 10 c.cm. of physiological saline solution may be used. The desire to give arsenic in large doses without its unpleasant effects has led to extensive trial of the various organic preparations. Cacodylate of soda, atoxyl, soamin, and others have all been used, but there is no convincing evidence that they confer greater benefit or do less harm than inorganic arsenic. Indeed, they may be more dangerous, since their toxic effects are more insidious in onset and sometimes of greater severity and duration. Herpes, pigmentation, neuritis, blindness, febrile attacks, and gastric disturbance are among the effects of heavy or prolonged dosage, and idiosyncrasy is not infrequent. The salvarsan group has had an abundant trial. Novarsenobillon is probably the least toxic, but its efficacy does not equal that of the inorganic forms. Granted a case in which arsenic is not tolerated by the mouth I would first try N.A.B. and, if possible, I would prefer to give it intravenously rather than intramuscularly. The pain of an intramuscular injection is a factor of some importance in the case of enfeebled patients.

There is no advantage in continuing to give arsenic after the blood count has reached the normal.

*Iron.*—In the average case of pernicious anæmia iron is not only useless, but often causes gastric irritation and headache. It is, however, of service in cases which are in remission. In these cases new red corpuscles may be rejuvenated rapidly and apparently the production of hæmoglobin cannot keep pace with them. The result is that the young corpuscles are poor in hæmoglobin. The criterion of this is the colour-index (the percentage of hæmoglobin divided by the percentage of red corpuscles taking five millions per c.mm. as 100), which should be estimated once a week.

Whenever the colour-index falls below 0·8 iron should be given. I have once or twice seen cases which had been making poor progress begin to improve after the administration of iron although the colour-index was high. This is exceptional, but the expedient may be worth a trial. The form in which iron is given matters little as long as an adequate quantity can be tolerated. Blaud's pill capsules and the tincture of perchloride, well diluted, are among the best.

---

* An article by Dr. Goodall on the Treatment of Chlorosis and Secondary Anæmia will appear in our next issue.

*Bone-marrow.*—Bone-marrow, red and yellow, raw and cooked, simple and compounded with spleen juice or other product of some irrelevant viscus has often been advocated and remissions following its use have been recorded. I have never been able to associate improvement with the use of bone-marrow.

*Normal Horse Serum.*—When arsenic fails horse serum is worth a trial. It is difficult to understand how it acts, but my favourable experience of it seems to amount to more than coincidence. It may be given hypodermically or even by the mouth in doses of 10 c.cm. When given by the mouth the nature of the substance should not be mentioned to the patient, as the idea of taking the serum may induce nausea.

*Transfusion.*—It is very difficult to assess the value of transfusion. Sometimes an apparently brilliant result is obtained, but the improvement is seldom long maintained. Much more frequently the effect is very slight and often no result may be obvious

In this connexion I may quote a remarkable case In 1910 a man, aged 46, complained of weakness and slight jaundice of five weeks' duration. His red corpuscles numbered 1·02 millions; hæmoglobin percentage was 30. He did not improve and it was resolved to try transfusion His wife's blood was of suitable group and rather over a pint was injected. Almost immediately the patient began to suffer from severe rigors, his temperature rose to 104° F., and the urine became deeply blood-stained. The blood films showed an enormous number of nucleated red cells. After being desperately ill for two days the patient began to improve. He was able to return to work as an electrician and remained well for five years. Weakness and anæmia then returned and advanced rapidly. Transfusion was tried, this time from another donor There was no untoward result, but no benefit followed and the patient died.

When transfusion is employed the citrate method is the most convenient. Sodium citrate 3·8 per cent. added to blood in the proportion of 1 to 10 prevents coagulation and is isotonic. Transfusion from donors suffering from polycythæmia has often been tried, but while the donor may be benefited there is no advantage over ordinary blood to the recipient.

*Vaccines and Sera.*—These substances are mentioned not from any belief in their efficacy, but because they have been extensively tried and inquiries regarding them are often made. When there is a septic focus which cannot be successfully treated by surgical means, the administration of an autogenous or homologous vaccine is legitimate. It must be remembered, however, that in pernicious anæmia the bone-marrow is so involved in domestic trouble that it has little reserve for dealing with a new stimulus. Since the success of a vaccine depends upon adequacy of reaction, the hope of benefit is but slight. A belief that the source of the causal toxin is the intestine has led to the use of autogenous vaccines made from the fæces. In my experience these are always useless and usually poisonous. Violent reactions may occur, but the patient does not improve. Antistreptococcus serum has been given under the mistaken idea that it meets a causal factor. It is useless and sometimes harmful.

*Splenectomy.*—This operation has no justification either in pathology or in experience. Probably only the more successful cases have been published, and the results of these are less favourable than those obtained by safer methods.

*Complications.*—Many conditions may complicate pernicious anæmia and must be dealt with on their merits. There is no special measure which tends to ward off the nervous conditions, such as combined sclerosis which often follow. It is important not to precipitate them by the excessive use of arsenic. It is worth mention that the pallor and facies of pernicious anæmia sometimes lead to the overlooking of a concomitant condition of hypothyroidism, and even when the latter has not been obvious I have sometimes seen success after a few speculative tablets of thyroid.

ALEXANDER GOODALL, M.D., F.R.C.P. Edin.,
Assistant Physician, Royal Infirmary, Edinburgh;
Lecturer on Clinical Medicine, University of Edinburgh.

# Special Articles.

## UNIVERSITY OF EDINBURGH.

### OPENING OF THE RECONSTRUCTED DEPARTMENT OF SURGERY.

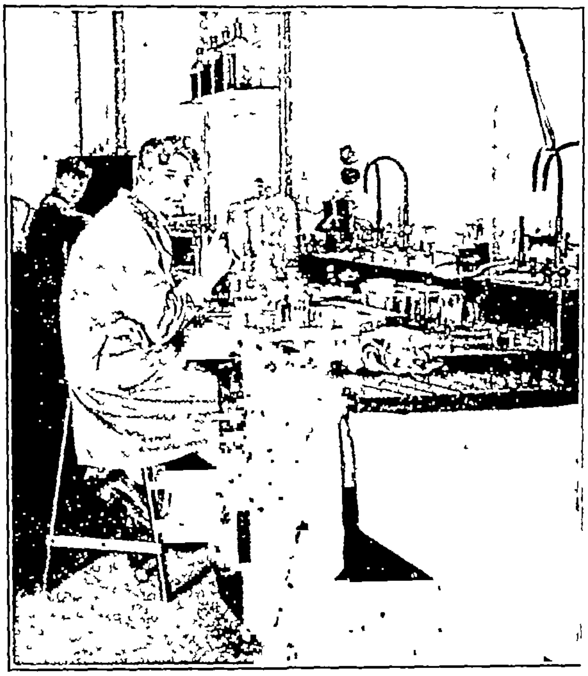
ONE of the principal events of the Bicentenary Celebration of the Edinburgh Faculty of Medicine is the formal opening of the reconstructed Department of Surgery to be performed by Sir John Gilmour, Secretary for Scotland, on Friday, June 11th. It was in July, 1924, that Prof. D. P. D. Wilkie was appointed to the chair of surgery under what were for Edinburgh new conditions—namely, on a "modified whole-time basis"—on which the professor devotes the major part of his time to his university and hospital duties, but is permitted restricted opportunities for private practice. The medical buildings of the University of Edinburgh were designed and built in the days when the didactic lecture formed the essential part of university education. Whilst extravagantly equipped with splendid auditoria, the building was ill-suited for the practical teaching and research which are the main functions of modern departments in all branches of medicine. Whilst in the departments devoted to the earlier subjects of the medical curriculum—e.g., physiology—well-equipped laboratories had been added, in that of surgery a small museum and a smaller laboratory for histological work were the only facilities available. A complete surgical department must make provision for the carrying out of two main functions—teaching and research. It was decided, therefore, to utilise the existing space, and by reconstruction to provide accommodation for practical and demonstration rooms and for an adequate teaching museum; for a research department a very considerable additional space was required.

#### *Teaching Department.*

The old surgical lecture theatre was large and lofty and was provided with a gallery. By flooring it across at the level of the gallery, an excellent auditorium was provided above and space for practical rooms obtained below. Three practical rooms were thus provided for the teaching of bandaging, surface anatomy, and operative surgery; one of them was fitted out for microscopic demonstrations. A small theatre, formerly used for tutorial classes, was converted into a teaching museum, extra wall space being obtained by building a gallery. The room which formerly served as a museum was fitted out as a students' reading room, in which naked-eye and microscopic specimens, illustrative of the subjects being dealt with in the lectures, could be displayed and studied at leisure. The old laboratories, consisting of three rooms on the ground floor of the building, were converted, one into a room for mounting museum specimens. The second room was turned into a photographic mounting room. The third room was divided into (*a*) a workshop with lathes, &c., (*b*) a chilled room for keeping bodies for the operative surgery class. To provide ready communication between the various parts of the Teaching Department and between it and the Research Department, an electric elevator was installed. In the basement of the building two rooms were equipped for all forms of photography. Wherever possible a clinical photograph and a microphotograph accompany each pathological specimen in all demonstrations. A very complete outfit of apparatus for microphotography, copying, enlarging, reducing, and for the rapid making of lantern slides was set up.

Whilst recognising that in the wards of the hospital the main burden of surgical teaching must be carried out, it is essential that the student should have a *thorough grounding in surgical principles* in applied anatomy and in surgical pathology. The teaching in the university department is designed to fulfil these objects. The student in his third year of study attends a course of lectures and demonstrations on the principles of general surgery, and is given practical instruction in bandaging and the treatment of fractures; in his fourth year he returns for a course of lectures and demonstrations in regional surgery and surgical pathology. For senior students in their final year a special course on surgical pathology is given by the senior assistant in the department, who is the university lecturer on this subject. In his fifth year the student attends a course on operative surgery. This class is divided into sections and the students perform on the cadaver the standard operations of surgery. In the summer session a special course on surgical pathology is held for graduates. In this course the professor and six other lecturers take part, each devoting himself to some subject of which he has made an especial study. This class offers an admirable opportunity to present the latest developments of surgical research and is of value both to teachers and taught.

FIG. 1.



Surgical Research Department, Histological Laboratory.

*Research Department.*

Accommodation for a Department of Experimental Research was obtained by the conversion of a two-storey building adjoining the Teaching Department. This building had been erected three years previously as an Anatomy Department for women students, and consisted of two very large and well-lighted dissecting rooms. By portioning off these rooms into smaller units and equipping them for the various needs of a Research Department, facilities were provided without the erection of a new building. The objects aimed at in the reconstruction of this building were:

(1) Facilities for the routine histological and bacteriological investigation of all pathological material from the clinical unit of the department and for the intensive study of certain material of special scientific interest from other clinical units of the hospital.

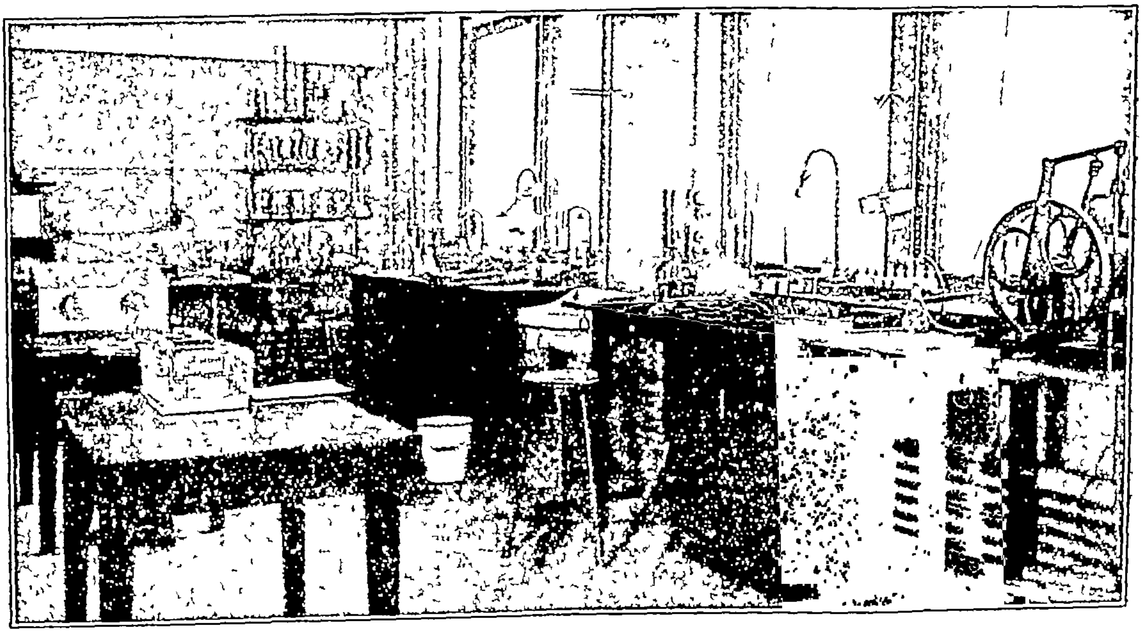
(2) The provision of a fully equipped Operating Department with all radiological and recording equipment, where operations could be conducted under conditions equal to, if not superior to, those found in a modern hospital. This part of the department is to be available to workers, not only in the Surgical Department, but also to those in all research laboratories of the University. It is then hoped that a fuller collaboration and liaison may be established between workers in the various branches of medical research.

(3) The provision of accommodation for individual research workers engaged either in experimental research or in the working up of material from clinical cases.

(4) The provision of a common room and library where workers may meet and where informal discussions will be held.

*Ground Floor* (*Plan A*).—On entering the research block we pass from the hall into a room for the reception of all fresh pathological material. This

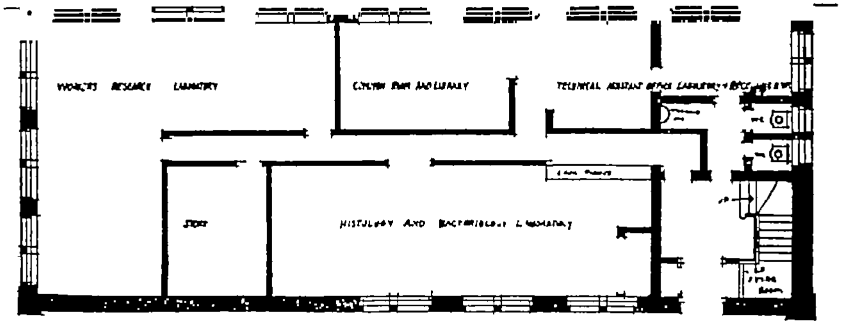
FIG. 2.



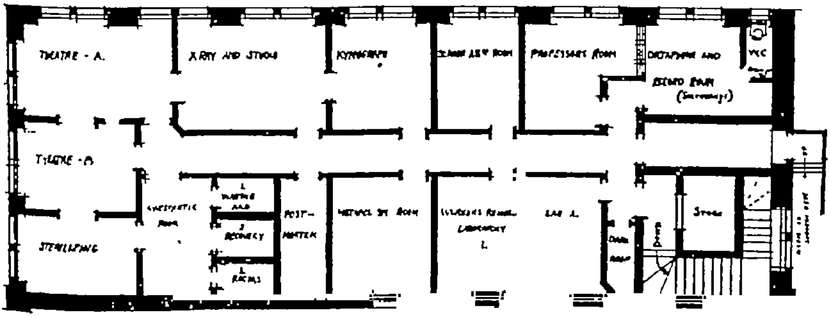
Surgical Research Department, one end of large Research Room.

room is provided with a large, shallow sink for the cleansing and assorting of large post-mortem specimens, with a broad bench on which material is indexed and filed by the chief technical assistant, whose room adjoins, before being passed on to the laboratory. On the ground floor is a large laboratory (Fig. 1) in which the technical workers carry out all routine as well as special histological and bacteriological work. It is equipped for all forms of section cutting, including large sections of entire organs. Beyond the technical laboratory is a store room for laboratory materials and special apparatus. Next we enter the *research laboratory* for graduate workers (Fig. 2). It is fitted with benches for 12 workers with cupboard accommodation for each on the opposite wall. Each bench is fitted with a sink with hot and cold water, with electric light and power plugs, with a two-way gas cock, and with an air pressure tap and suction tap. Air pressure and suction are laid on throughout the entire building, the force being generated by motors in the power house. At the ends of this room, which is of L shape, are electric paraffin ovens, incubators, centrifuge and Gerrick pump. In this room the current scientific journals are available and standard works of reference are stored. The workers are encouraged to meet here daily for informal discussions and to exchange views with workers in other department.

PLAN A.—*Ground Floor.*



PLAN B.—*First Floor.*



*First Floor* (*Plan B*).—On this floor are the private laboratories of the professor and the assistants in the department. Each is fitted with the same equipment as the large laboratory. A kymograph room is equipped with recording apparatus which is of portable type and can be moved to the operating theatres. In direct communication with both the kymograph room and the larger of the two operating theatres is the X ray room. In this is installed the full apparatus for radiography of both the human subject and experimental animals. A small emergency dark room for rapid developing is placed on this floor in close proximity to the X ray room. There are two *operating theatres*, one of which is fitted for radiographic observations during operations. The theatres are floored with rubber; they can be steamed before operation so as to obtain a sterile atmosphere. These are lighted from above and from the sides and artificially by means of daylight lamps placed above a glass false roof. Hot and cold sterile water and saline solution are laid on by pipes from the sterilising room, and in both rooms, below the operating table, is a rubber-covered trap-door concealing a box in which are to be found two electric light plugs, three electric power plugs, an air pressure tap, and a suction tap. By means of a wind-screen wiper the air pressure and the suction can be made intermittent. By partly raising the trap-door leads from these fittings can be brought directly up to the operating table and thus a head lamp, an electric cautery, intratracheal anæsthesia, and suction swabbing of the wound can be utilised without the inconvenience of leads and other apparatus obstructing the theatre. To obviate the collection of dust on the false glass roofs of the theatre, these are made to slope to either side from a central spar along which is led a water sprinkling pipe, by means of which the glass may be washed from above by merely turning a tap. The sterilising room is fitted after the usual hospital pattern with high pressure steam autoclaves, instrument and basin sterilisers, and hot and cold water and saline sterilisers. Adjoining the theatre is the anæsthetic room. Off the anæsthetic room open three specially heated recovery rooms for animals after operation. Besides the protected steam pipes which pass through these rooms, plugs are provided for the supply of electric mats for cases in which the supply of warmth is of special importance. A small post-mortem room completes the operating department, which is floored throughout with rubber and can be flushed with water in its entirety. A biochemical room is equipped for chemical investigation in relation to experimental work and will have a close liaison with the corresponding clinical laboratory in the hospital. A small room, which can be steamed to provide a sterile atmosphere for inoculating culture media and for post-mortem examinations in which bacterial contamination must be rigidly excluded, is found at the entrance to the experimental floor. Adjoining the professor's room on the experimental floor is the dictaphone and stenographer's room, where records of experiments can be made without delay.

*Animal Houses.*—Direct access from the experimental floor is obtained by means of a covered bridge and gangway to the newly constructed animal houses and to the elevator leading to the teaching department. In order to meet the greatly increased demands for experimental animals the animal houses, formerly a collection of one-storey buildings, have been doubled in size by building a second storey. Central heating is provided throughout, the walls are of glazed Keen's cement and can be easily flushed down. The windows and roof lights are of Vita glass to permit of the passage of ultra-violet rays, and next the operating department is a bathroom, fitted for washing animals before operation.

# A VISIT TO SOME OF THE WEST GERMAN SPAS.

OPPORTUNITIES were recently given to representatives of the *British Medical Journal* and THE LANCET to make an official tour of spas in Western Germany, of which little has been heard in this country since 1914. Ten spas were visited, and the brief notes which follow are given in the order in which the visits were paid.

## NEUENAHR.

This little spa is situated in the valley of the river Ahr, a few miles from the point where it joins the left bank of the Rhine, and is reached by train from Cologne in about two and a half hours. It is a well-wooded, sheltered place with clean, smooth gravel paths and roads which make walking possible immediately rain ceases. The Kurhotel, with its 350 rooms, said to be the largest hotel in West Germany, is modern and comfortable, and its kitchens are models of cleanliness and efficiency. Facing the Kurhotel, and separated from it by lawns and gravel paths, stands the Kurhaus (i.e., Casino) with its band-stand, concert-room, theatre, café, dancing hall, and American bar. Here the young and the holiday makers can amuse themselves without disturbing those who are taking the cure. Behind the Kurhaus, and separating the spa grounds from the small town, runs the little river Ahr, which has the appearance of a good fishing water and is said to be well stocked with trout. The spa grounds contain the warm, ferruginous, highly carbonated springs, the discovery of which led to the development of this place some 70 years ago. The bath establishment adjoining the Kurhaus contains 120 bathrooms, mostly constructed for giving only simple immersion baths in the thermal water; there are also rooms for massage, packs, and various electrical treatments, but it is evident that these accessory treatments are of secondary importance.

Neuenahr specialises in the treatment of diabetes and obesity and of sufferers from gastric and duodenal ulcer. Here more attention is given to diet than in most German spas, and in the Kurhotel all menus are divided into three parts; the first the ordinary menu, the second for those with digestive troubles, and the third for the diabetic and obese. The essential features in the diabetic diet are the provision of special breads, biscuits, and puddings with low carbohydrate content but still quite palatable, and the substitution of saccharine for sugar in cooking. The use of the waters is empirical and there is no up-to-date laboratory for clinical investigations. Urinary sugar is estimated, but blood sugars are estimated only in the presence of acetonuria, and, as coma is said to be almost unknown during treatment, it must be assumed that severe cases of diabetes form a small minority of the cases sent here. But with the water drinking and bathing, diet, and graduated exercise it is said that good results are obtained.

The place has an attractive simplicity and shows what can be done in the development of a small spa without lavish expenditure, provided that the local waters and surroundings are suitable.

## EMS.

Ems lies in a deep, rather narrow valley, the configuration of which is reminiscent of Matlock Bath. In the bottom of the valley runs the river Lahn, which is big enough for rowing and sailing regattas to be held here. The town is about equally divided by the river, which is conveniently bridged. Some of the warm springs contain 2 g. of sodium bicarbonate and 1 g. of sodium chloride per litre, this quantity of water yielding from 500 to 600 c.cm. of free carbonic acid gas. The hydrotherapeutic and electrical equipment are modern, and there is a clinic with a State doctor in charge of biochemical and bacteriological laboratories and of the X ray outfit and electrocardiograph. Whilst it is claimed that all catarrhal conditions from eye to bladder benefit by Ems treatment, it is best known for the treatment of bronchitis, asthma, emphysema, and their secondary cardiac disturbances. The pneumatic compression chambers, inhalation, gargling, and spraying rooms are well constructed and provide accommodation for large numbers of patients.

## LANGENSCHWALBACH.

Langenschwalbach may be reached from Ems by car through the forests covering the Taunus mountains. On the hillside are the large barracks built for the French Army of Occupation, which have recently been taken over by the British. The iron drinking waters are used in the treatment of anæmia and dyspepsia. Carbonated chalybeate waters are also used for immersion baths, but best known of all are the chalybeate mud baths, of which some 6000 a year are given for inflammatory conditions of the pelvis, rheumatism, and chronic fibrositic conditions. The rather deserted appearance of this little spa in the hills is probably due in part to a fall in the pre-war number of 6000 visitors per annum to about 2000 at the present time, but it has an attractive and restful look.

## SCHLANGENBAD.

This is a pretty hillside health resort among the woods where the wells are carbonated water of low mineral content. The "steam bath," in which the water flows continuously through the bath, has been found useful for skin diseases; Schlangenbad is a suitable place for rest cures and here come people suffering from insomnia, neurasthenia, and nervous breakdown.

## WIESBADEN.

Wiesbaden lies at the foot of the Taunus Mountains and is a handsome, modern city with beautiful surrounding woodlands. The splendour of the Kurhaus and of the Kaiser Friedrich Bad, completed in 1914 regardless of expense, is somewhat overwhelming. Sodium chloride is the chief mineral constituent of the hot springs, and gout and rheumatism are the complaints for which these waters seem most suitable, but the equipment of the bathing establishments is so complete that practically all diseases amenable to spa treatment can be dealt with. At the general hospital, of which Dr. Geronne is in charge, there is also a well-equipped balneotherapeutic department. One half of this hospital is at present occupied by the R.A.M.C. as the central hospital for British troops in occupied territory. Several of the private hotels, such as the "Four Seasons," have their own thermal springs and bath houses, so that patients can take their immersion baths with the minimum amount of trouble.

### KISSINGEN.

There is an old-fashioned stateliness about Kissingen and a quiet dignity even in its newest spa buildings which is very restful and in pleasing contrast to the more ornate decoration seen elsewhere. The balneological plant is modern, and experimental work in the collection, analysis, storage, heating, and manipulation of the highly carbonated saline waters is carried out by an able chemist, who is the State mineral water engineer for this and other Bavarian spas. Dr Granville's letters to the *Times* in 1850, describing the wonders of the newly discovered great artesian salt spring issuing at a temperature of 66° F., may in part account for the large number of English visitors of former times. The cold saline water contains an exceptionally large quantity of free carbonic acid gas. Chalybeate waters and mud baths are used, and the complaints mainly treated are diseases of the digestive system, arterio-sclerosis, gout, and rheumatism.

### NAUHEIM.

Nauheim was well known to English people in pre-war days. The free supply of carbonated saline chalybeate waters issuing at a temperature suitable for bathing without artificial heating or cooling, and in various strengths of saline content and free carbonic acid gas, explains in part why the spa became known as a health resort for people suffering from circulatory disturbances. The mineral water engineering here is particularly interesting. Carbonated saline waters are common in Germany, and other spas claim to give treatment for disorders of the heart as well as Nauheim. The arguments current there as to the absorption or the reverse of carbon dioxide through the skin, as to the different action of artificial and natural $CO_2$, and as to the importance of the proportions of sodium and calcium salts to one another and to other salts are entertaining if not convincing. In Nauheim, however, the dogmatist of the combined auscultation-percussion method, with his gradually diminishing blue-pencilled outlines of the heart, is somewhat curbed by the orthodiagram, electrocardiogram, and galvanometer. The State clinic, where these controls are employed, is under the direction of Prof. Weber, who has further research in view. At one private clinic, run on "Duff House" lines, both investigation and treatment are on up-to-date lines. All forms of heart disease are treated in Nauheim, but renal calculus, chronic Bright's disease, and recent cerebral hæmorrhage are regarded as *contra-indications.* Whilst the modern spa physician does not claim to reduce the size of the old hypertrophied heart, he does claim to improve functional efficiency in suitable cases.

### WILDUNGEN.

This small spa lies in a little valley surrounded by leagues of hill and forest. There are several springs, the principal one being a carbonated iron water containing little sodium chloride. A large business is done in bottling and exporting the waters which are best known for their action in diseases of the urinary system. Contracted granular kidney, stone, enlarged prostate, cystitis, and the like are treated here, but the large white kidney with marked albuminuria is not considered suitable for these waters. The baths are built in the ground floor of the large Furstliches Badehotel, where are Turkish baths, douche, and inhalation rooms, although the water, drinking and bathing, are considered the most important parts of the treatment. Ten kilometres away in the River Eder there is excellent trout fishing, at all events for the provident angler who has brought the necessary tackle with him.

### PYRMONT.

Pyrmont is renowned for its mud baths, of which some 300 are given daily, in addition to about 1500 mineral water baths in the full season. They have a high reputation in the treatment of sterility in the female, and it is the custom for young brides from the surrounding country to come here for a course of baths if pregnancy does not result within a reasonable time after marriage. The baths are also used for post-operative and other inflammatory conditions of the abdomen and pelvis. The six chalybeate springs have varying quantities of iron and saline, and one used solely for bathing has a large quantity of carbonic acid. There are also radio-active brine springs besides the enormous quantities of mud, which in this neighbourhood contain sulphuric acid and ammonia. The gardens of Pyrmont are a notable feature, and the presence of palms and other subtropical trees indicates a mild climate.

### OEYNHAUSEN.

This has been termed "the town without steps." The district is flat, and for the convenience of patients taking the cure, and especially those in bath chairs, little slopes take the place of steps wherever possible. The carbonated saline waters come from a depth of 700 metres and the free gas in consequence comes off more slowly than from most other springs. One litre of water yields 900 c.cm. of carbon dioxide. A new spring with a high calcium chloride content is now being bored and is expected to be of value in the treatment of heart diseases. *There are also* saline baths without carbon dioxide. Diseases of the central nervous system, gout, rheumatism, and circulatory disturbances are all treated here. The newcomer is at once struck by the large number of patients in bath chairs. This is not entirely accounted for by the numbers of paralysed and lame people who come here for treatment, but because the local doctors favour this form of "carriage exercise" as a means of ensuring the requisite number of hours rest for those taking the cure. The town is surrounded by a lovely park with well-kept paths and seats at convenient intervals.

## PARIS.

(FROM OUR OWN CORRESPONDENTS.)

### *The Witness of Psychopaths.*

AT the recent Congress of Legal Medicine Dr. Roques de Fursac, medical officer to the Mental Hospital of Ville-Evrard, read an interesting report on the witness of psychopaths, considered both from the point of view of truthfulness and of knowledge; the former being determined by the ratio of exact declarations to the sum of exact and false ones, the latter by the ratio *of exact declarations* to the total questions asked. Generally speaking, the witness of psychopaths is inferior to that of the sane, but a certain number are found whose coefficient of truth is equal or superior to the lowest coefficient in sane persons. The witness of the psychopath cannot, therefore, a priori be turned down. Provisionally psychopathic states can be graded in regard to fidelity of witness in the following diminishing order: melancholia, chronic delusional psychoses, chronic hallucinatory psychoses, mania, cerebral traumatism, schizophrenia, mental retardation, epilepsy, general paralysis, senile dementia, and cerebral arterio-sclerosis. The extent of knowledge shown by the *psychopath is generally* very slight, much slighter than its truthfulness. It is manifested in the small number of questions answered rather than in the number of errors committed. Knowledge is generally good for spacial relations and for acts, bad for personal description, colours, words, localisations in time and duration. Psychopaths are very unequally suggestible. From the point of view of suggestibility the author classes the states in descending series as follows: mental retardation, epilepsy, general paralysis, senile dementia and cerebral arterio-sclerosis, schizophrenia, mania. In melancholia and in chronic hallucinatory psychoses patients are completely refractory to suggestion. The value of a psychopath's witness is always a question of degree and can only be fixed by an expert in credibility.

### *A Service of Functional Recuperation at the Salpêtrière.*

Prof. Guillain has communicated to the Academy of Medicine the results obtained at the Neurological Clinic of the Salpêtrière in a service organised there for two years past by Dr. Gabriel Bidou. His method of functional recuperation has nothing in common with the orthopædic method. It implies collaboration of the neurologist with a physiologist who is both something of an engineer and a mechanician. The apparatus required is the result of special mechanical study based on physiological principles and the general laws of mechanics. Knowledge of pulleys, levers, points of rupture and angles of flexion are, for example, all required to put a paralytic on his feet and to give him the means of locomotion. Thus conceived and realised this ensemble of mechanical factors designed for restoring human function constitutes a veritable treatment which adds substantially to the resources of neurological therapeutics. Old paralytics, completely helpless for years, who might have remained all their life at the Salpêtrière have been enabled to leave the hospital and take up some occupation, and in this way the charges on the Assistance Publique have already been substantially lightened. From the medical point of view there is a humanitarian rôle to fill in restoring to family life patients previously condemned to institutional existence.

### *Sunday Closure of Pharmacies.*

The Pharmacists' Union has received Governmental support in requiring pharmacists to close on Sundays and public holidays, one pharmacy to remain available in each arrondissement. A number of pharmacists who opposed this ruling and kept their shops open have been heavily fined, and the opposition is weakening. One pharmacist bowed to the inevitable but draped his doorway in black with a representation of a tomb and cross-bones, and an ironic epitaph on the injustice of the legal order.

### *Increased Family Premiums.*

Provisions materially increasing the premiums awarded to large families recently became effective. Families counting four children or more, aged less than 13 years each, may receive Fr.360 annually for each child, beginning with the fourth. A family of five children would therefore receive Fr.720, a family of six Fr.1080, and so on. Provisions also extend to widows and widowers. A widow having six children would receive Fr.1800 yearly. The increased premiums are actuated by the desire to encourage repopulation.

Dr. Edmund Landolt, well known for his work on refraction and other branches of ophthalmology, has just died at the age of 79. Born in Switzerland, he became naturalised as a French citizen. His two sons served with the French in the world war. He was occupied with studies on refraction to the very moment of his passing.

A convention, ratified by the Government, will lead shortly to the union of the Institut de Cancer with the Faculté de Médecine of the University of Paris. This move toward centralisation is likely to promote greater efficiency in the measures directed against cancer.

The twenty-sixth French Congress on Urology will open on Oct. 5th under the presidency of Prof. Marion. The chief subject for debate is the Vesico-ureteral Reflex. Information from Mr. O. Pasteau, 13, Avenue de Villars, Paris, 7e.

At the International Dairy Congress being held in association with the *foire de Paris*, or annual Paris fair, it was suggested that milk should be classed according to its food value in terms of fat content and according to the purposes to which the milk is to be put, the price being graded accordingly.

Prof. Sébileau, chief of the oto-rhino-laryngological service of the Lariboisière Hospital, has been presented by his friends, colleagues, and students with a fine bronze medal.

Prof. Prenant's courses in histology, suspended on account of students' demonstrations, have been resumed without further incident.

The municipal institute of electro-radiology in the Boulevard St. Marcel, Paris, planned 12 years ago, progress being interrupted by the war, was inaugurated on May 21st.

A Bill proposing to make tuberculosis notifiable has been sent by the Chamber of Deputies to the Committee on Hygiene for examination.

The centenary of Laënnec's death was at Montfort-l'Amaury celebrated on June 6th. His effigy is to appear on the postage stamps of the antituberculosis crusade.

## BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

### *Unsatisfactory Results with the Dick Test.*

Dr. Jenö Kramár has made extensive experiments in the University Pediatric Clinic in Pécs in the application of the Dick test. His experiences do not seem to corroborate the views of the American authors, who have published enthusiastic reports on the reliability of this test. Dr. Kramár says that those children who were alleged to have suffered from scarlet fever gave positive reactions in practically the same percentage (60 per cent.) as did those who had no history of the infection (58 per cent.). These results could hardly be explained on the basis that the history given might not be reliable. Dr. Kramár found also that serial tests made on the same subject gave different results: the child who gave a negative reaction in the first instance later became positive, and afterwards repeatedly negative. The question arises: Are we justified in regarding a child as immune to scarlet fever because of the negative result of a single test? His experimental results suggest that the reaction in scarlet fever patients does not follow such a strict rule as American authors would have us believe. One-third of the observed scarlet fever patients gave a strongly positive reaction, even in late convalescence; on the other hand, the reaction was negative in other cases even at the outset of the disease on the second and third day. On these grounds Dr. Kramár doubts whether the Dick test could be advantageously used in establishing the diagnosis of scarlet fever.

### *Diseases Acquired by Hospital Workers.*

Prof. Dr. Gerlóczy, managing director of the St. Ladislaus Hospital for Infectious Diseases, and lecturer to the Budapest University, publishes interesting and instructive data in the last number of *Egészség (Health)*. According to the statistical data of St. Ladislaus Hospital during the period 1917 to 1925, out of 176 physicians rendering service as junior, assistant, and senior physicians, 104—that is, 59 per cent.—contracted some infectious disease. Among these there were 33 cases of tonsillitis, 32 influenza (with one fatal case), 5 scarlet fever, 3 typhoid fever, 3 angina, 12 cases of dysentery, 4 epidemic conjunctivitis, 2 nephritis, 2 cellulitis, 2 pleuritis, and 1 diphtheria, 1 erysipelas, and 1 epidemic enteritis. Among the clerks of the hospital 12 contracted diseases and 4 of them died. Among the nurses, 630 contracted infectious diseases, and of these 30 died. Out of the auxiliary staff (servants, laundry women, cooks, &c.), 78 fell ill, with 9 fatalities. The statistics relating to the latter two categories nurses and auxiliary staff, cover the period between 1910 and 1925, while those relating to the clerks cover the period commencing with 1918

### *Lottery in Aid of Aged and Incapacitated Physicians.*

The Ministry of Finance has licensed the Association *for the Assistance of Incapacitated and Aged Physicians* to issue lottery tickets, any profits accruing being allotted to the help of the beneficiaries of the Association All administrative work will be done by volunteers. Though the Association only called for medical volunteers to offer their services many lay people of all ranks and classes have volunteered to show their sympathy with indigent doctors 30,000 lottery notes will be issued at about 6*d* each, and the management hopes to make a net profit of about a thousand pounds. As the sale of the tickets is likely to be pushed by all doctors, and particularly by those living in the country, it is hoped that the enterprise will be a success.

### *The Spread of Goitre in Hungary*

The Ministry of Public Welfare has compiled statistics on the spread of goitre in Hungary According to the data published the number of adult goitre patients has not increased On the other hand, there is a very large increase in goitre among school children, particularly among girls The percentage of the occurrence of goitre among school children is 2 38; that is very low in comparison with certain other lands, as, for instance, Switzerland, where 60 80 per cent. of school children suffer from goitre, or Austria, where the figure is 25–40 per cent. The institutions established by the Ministry of Welfare for the checking of even this small number of goitre cases appear, judging by the statistics, to be doing good work.

### *The Mortality rate of Budapest*

In the second half of last year the mortality rate of Budapest was exceedingly great. In fact, the only capital in Europe which exceeded the Budapest rate is Warsaw The Hungarian Ministry of Health is greatly concerned about this state of affairs, though the rate is a considerable improvement on that for the corresponding half of 1924 The mortality rate per 1000 was 17 in Lithuania for the year 1924 and fell to 14·2 in 1925 Since in all other European capitals excepting Oslo the rate of mortality appears to be on the increase, the fact that some improvement is taking place is encouraging

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 29TH, 1926

*Notifications*—The following cases of infectious disease were notified during the week: Small pox, 103 (last week 162); scarlet fever 1088; diphtheria 379; enteric fever, 80; pneumonia, 990; puerperal fever 45, cerebro spinal fever 7; acute poliomyelitis, 3; encephalitis lethargica, 42; trench fever 1; dysentery, 4; ophthalmia neonatorum, 90 There was no case of cholera, plague, or typhus fever notified during the week.

In London itself there was notified no case of small pox; scarlet fever 250 diphtheria 234; enteric fever, 9; pneumonia 96 puerperal fever, 6; cerebro-spinal fever 1; acute poliomyelitis 1; encephalitis lethargica, 4; and ophthalmia neonatorum 9

*Deaths.*—In the aggregate of great towns including London there were 1 (1) death from enteric fever, 36 (12) from measles, 6 (2) from scarlet fever, 25 (3) from whooping-cough, 10 (2) from diphtheria 15 (8) from diarrhoea and enteritis under 2 years and 78 (15) from influenza. The figures in parentheses are those for London itself

(The Registrar General's weekly return had not appeared as we went to press and we are indebted to the Ministry of Health for these figures.)

---

THE Minister of Health, Mr Neville Chamberlain, will distribute prizes at the *London Hospital Medical College* and Dental School on Monday, June 28th at 3 P.M Academic dress will be worn at the distribution which takes place in the College Library, and there will be tea and music in the garden

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

Surg Comdr W T Haydon is placed on Retd. List with the rank of Surg Capt.

Surg Lts W H Bradfield to the *Hermes*, J C Souter to the *Emperor of India* J W Tighe to the *Herald*, J Mitchell and J C O Boyle to the *Defiance*, temp., and A. E. Phillips to the *Dolphin*, for special duties and to the *President* addl., for R.N College, Greenwich, for course of instruction at Medical School.

### ROYAL NAVAL VOLUNTEER RESERVE.

Proby Surg Lt. (D) E. D Collins to be Surg Lt. (D)

## ROYAL ARMY MEDICAL CORPS

Maj Gen Sir M. H G Fell, late R.A.M.C, to be Deputy Director-General at the War Office, vice Maj Gen. C E. Pollock, K.H S., who retires on retd pay

Maj and Bt Lt-Col. S. L. Pallant to be Lt.-Col., vice Lt-Col C W Holden to ret. pay

Capt. A. G P Hardwick retires, receiving a gratuity

### SUPPLEMENTARY RESERVE OF OFFICERS

Lt. A. R. Balmain to be Capt.

### MILITIA

Capts. G Perkins and I. D Evans to be Majs.

### TERRITORIAL ARMY

Lt G A MacDonald (late R.G.A., Spec Res) to be Lt.

Lt. E. H Ponder resigns his commn.

R. W Power to be Lt.

A. L. Moorby (late Temp Lt., R.A.M.C) to be Lt

Maj-Gen. R. S. Hannay, C M G, D.S O, late R.A.M.C, has been appointed Hon. Surg. to the King, vice Maj Gen. H. A. Hinge, C B, C M.G, D S.O, late R.A.M C., retd.

## INDIAN MEDICAL SERVICES.

Dr G. W Bamford is appointed Resident Assistant Surgeon, Government Headquarters Hospital, and Lecturer in Materia Medica, Medical School, Tanjore, vice Dr A. P. Kuriyappam. Major P B. Bharucha, Professor of Anatomy, is appointed Professor of Operative Surgery, King Edward Medical College Lahore, vice Captain S N Hayes transferred. Dr Said Uz Zafar Khan, Principal, King George's Medical College, Lucknow, has been appointed a Member of the Board of Public Health, United Provinces vice Major H Stott, O B.E., resigned Captain H C. Tait, from Quetta, has been appointed Officer Commanding, Indian Station Hospital at Nasirabad, vice Major H de S B Herrick. Major H. Illingston acts as Professor of Medicine, Calcutta Medical College, during the absence on leave of Lieut.-Colonel F A. F Barnardo Major E. H. V Hodge Surgeon to the Governor of Bengal, acts as Professor of Clinical Medicine, Calcutta Medical College. Lieut-Colonel A. H Proctor, Civil Surgeon, Darjeeling, acts as Surgeon to the Governor of Bengal. Dr B. R. Brahmachari, officiating Director of Bengal Public Health Laboratory, acts as Professor of Hygiene in the Calcutta School of Tropical Medicine vice Lieut.-Colonel E B Fry Major A A C. McNeill officiates as Deputy Assistant Director of Medical Services (Mobilisation) Rawalpindi District vice Major A Kennedy Captain P H. S. Smith officiates as Deputy Assistant Director of Medical Services (Embarkation) at Bombay, vice Major C T V Benson Captains J Dunlop and R A. Murphy, Auxiliary Force Medical Corps have been awarded the Indian Volunteer Long Service Medal.

The following have been granted leave: Major D Sandes, Professor of Clinical Medicine, Medical College, Calcutta, Lieut. Colonel E. Waters, Surgeon Superintendent, Presidency General Hospital, Calcutta; Dr R S. Keelan, Deputy Superintendent, Mental Hospital, Agra, and Dr S. H Commissariat, Superintendent, Medical Aid for Women, United Provinces.

## TERRITORIAL ARMY AMBULANCE CHALLENGE SHIELD

The annual competition for the Territorial Army Ambulance Challenge Shield will take place at the Duke of York's Headquarters Chelsea, on Saturday June 26th, at 2 P.M. The competition is open to squads of Territorial Army medical units and of recognised stretcher bearers borne on the establishment of other units of the Territorial Army

# Correspondence.

" Audi alteram partem."

## THYROID ENLARGEMENT AND THE "LACK OF IODINE" THEORY.

*To the Editor of* THE LANCET.

SIR,—The following facts concerning the incidence of thyroid enlargement among the school-children of Hull, and the absence of iodine from the drinking-water of the city, strongly support the thesis of Sir James Berry in his Hunterian Lecture, published in your issue of Feb. 6th last, that lack of iodine is not the cause of endemic goitre.

In March, 1924, Sir George Newman issued a request to school medical officers that all cases of thyroid enlargement among school-children of the age of 12 years should be recorded, defining the condition by stating that only cases in which the enlargement was visible should be counted, and that measurements need not be taken. From the date of the letter until the end of that year 4103 children of the required age were examined in Hull; and only 14 (0·34 per cent.) showed any enlargement, the percentages for the sexes separately being: boys 0·26, girls 0·43. Among the records of other towns may be noticed Liverpool (situated like Hull on an estuary), the percentages here being: boys 0·33, girls 1·38; among inland towns, Leicester: boys 0·81, girls 2·51; Sheffield: boys 1·0, girls 4·4; while in Bristol the percentages were: boys 4·44 and girls 9·78.

As regard Hull, before any children had been examined, steps were taken by one of us (A. R. T.) to ascertain the proportion of iodine in the city supply water. Numerous methods have been proposed for the determination of minute amounts of the halogens (especially bromine and iodine) in natural waters, but the process of Fresenius is commonly followed.

In this method, a considerable volume of the water (20 litres or more) is evaporated to low bulk, after making distinctly alkaline with sodium carbonate, when the insoluble salts are removed by filtration and washing, leaving a filtrate containing all the soluble halogen salts. This filtrate is again concentrated and poured into three volumes of alcohol of 96 per cent. (weight) strength. Sodium chloride and other undesired salts largely separate out, leaving the bromine- and iodine-containing salts in solution. After standing overnight, the solution is filtered, the alcohol distilled off after making the liquid alkaline with a little caustic potash solution, and the residue diluted with water. 20 c.cm. of carbon disulphide (or chloroform), sufficient dilute sulphuric acid, and 10 drops of a saturated solution of nitrous acid gas in sulphuric acid, are now added, and the mixture well shaken. After the addition of more nitrous acid to ensure liberation of all the iodine present, the carbon disulphide is separated and the aqueous solution extracted twice more with further quantities of carbon disulphide. The mixed carbon disulphide solutions are washed with water till free from acid, and then titrated, after adding sodium bicarbonate solution in excess, with standard thiosulphate solution till the solvent has become colourless.[1] Bromides remain in the aqueous solution. A modification of the above process, stated to be so delicate as to detect quantities of iodine so small as those of the order of $3 \times 10^{-7}$ g., consists in the extraction of the acidified salts of the water, treated as before with sulphuric and nitrous acids, with carbon disulphide or chloroform, finally concentrating the solvent by careful evaporation at a low temperature to about 0·02 c.cm., and determining the strength of the colour left in the drop of solvent. For success with these methods it is essential that large volumes of the water be operated on.

No detectable trace of iodine was obtainable from the deep well chalk water supplied to the city of Hull by working in this way; indeed, it would appear that natural deep well waters from the chalk do not contain any appreciable proportion of bromine or iodine compounds. The last named are generally found in highly saline waters containing much sodium chloride and other chlorides; deep well chalk waters contain only very small amounts of chlorides and other salts, except calcium bicarbonate. There is thus no reason to connect the low incidence in Hull of enlargement of the thyroid gland with any action of iodine contained in the drinking-water. The Hull city supply of water is of great organic purity, crystal clear, and needs no filtration nor other treatment before distribution through the mains. Its hardness is: permanent, 6·5 to 7·5; and temporary, 14·0 to 17·0 parts per 100,000, as determined by the soap test and expressed as $CaCO_3$. It is therefore further evident that excess of dissolved calcium carbonate can scarcely be the effective cause of endemic goitre, though water derived from limestone has been suspected to be so. According to Colonel R. McCarrison, it is the presence of undissolved (suspended) matters in drinking-water that is the cause of this disease, and he quotes an instance of a school in which many cases occurred when the water was drawn from a contaminated source; when an unpolluted supply was obtained no new cases appeared.

The suggestion that sea breezes may carry enough iodine to supply the deficiency in the drinking-water might apply to Hull or Liverpool, but it is negatived by the figures from Bristol. If the lack of iodine theory is disproved, it renders unnecessary the addition of iodine to the drinking-water; persons affected by the disease can then be medicinally treated, the risk of causing hyperthyroidism in susceptible persons will not be incurred, and the considerable expense of treating large quantities of water will be saved.

We are, Sir, yours faithfully,
JAMES W. FRASER, M.D., C.M., M.R.C.S.,
School Medical Officer, Hull.
ARNOLD ROWSBY TANKARD, F.I.C.,
May 31st, 1926. City Analyst, Hull.

---

## CHOLECYSTOGASTROSTOMY FOR GASTRIC ULCER.

*To the Editor of* THE LANCET.

SIR,—Mr. Braithwaite's suggestion to replace gastro-enterostomy by cholecystogastrostomy in the treatment of gastric ulcer seems to me open to the objection that stomach contents can flow as easily into the gall-bladder as bile into the stomach. He based his operation on the success of the technique of cholecystogastrostomy performed for obstructive jaundice due to pancreatic disease (cancer or fibrosis of head); but here we have a more or less constant positive pressure in the gall-bladder. I would like to suggest to him that a more suitable operation would be on the lines of Roux's gastro-enterostomy, inplanting the distal end of the cut jejunum into the stomach as Roux did, but using the proximal cut end to implant into the stomach as near the ulcer as possible; this would ensure *all* the alkaline digestive juices being sprayed on the ulcer which I believe he mentioned in his article as being possibly desirable. (The pylorus, of course, would be closed.)

That the present gastro-enterostomy operation is not the last word in technique or treatment I quite agree. I have always, until the last one I did, performed it on the lines of Sherren's technique no loop-posterior-vertical. While most of them have done perfectly and have remained well, I nearly lost one and my senior surgeon did lose another from persistent vomiting. My case was saved by entero-enterostomy between the efferent and afferent limbs of the jejunal loop; the other case did not survive the second operation. In both cases the stomach and afferent limbs were distended, discoloured, and boggy. Personally, I think there is much too small a margin of safety in the technique and that obstruction easily occurs from kinking. I believe the so-called paralytic vomiting is always obstructive and that in the cases where this is overcome by lavage, &c., the stomach and jejunum eventually settle down into a position where the *efferent* limb is unkinked and the stomach is able to pass its contents into the efferent limb.

---

[1] See Sutton's Volumetric Analysis, eleventh edition, 1924, p. 235; and Treadwell and Hall, Analytical Chemistry, vol. ii., p. 521, for further details.

In the future I am fully determined to do only Roux's operation. It takes longer, but is as far as I can see an absolutely safe kink-proof operation and the one I have done had perfect immediate and after results. While on the subject of gastric ulcer I would like to mention the treatment of perforated gastric ulcer. There seems to be a tendency now to treat perforation by suture and immediate gastro-enterostomy. I cannot believe this to be anything but a pernicious doctrine. First, gastro-enterostomy is a big strain to put on a severely shocked patient and in the most competent and rapid hands will entail an addition of round about 20 minutes to the operation; and, secondly, the end-results of several years of experience as a general practitioner-surgeon do not seem to justify any addition to the technique of burying the ulcer by purse-string suture.

On points like this the G.P.-surgeon may safely say a word. If he cannot quote hundreds of cases yet he has to live with his patients afterwards, and I can definitely say that as long as the perforation can be closed and the ulcer turned in without practically closing the pylorus, the end-results lasting in many cases for years, 15 at least, have been excellent. I have only once had to do a secondary gastro-enterostomy after an operation for perforated gastric ulcer, and my experience is that involution cures the ulcer and the stomach rapidly accommodates itself to the deformity produced by this operation. In the case mentioned suturing produced so much pyloric narrowing that I had to do a gastro-enterostomy a fortnight later.

I am, Sir, yours faithfully,
R. LEONARD LEY,
Assistant Surgeon, Great Yarmouth Hospital.
May 31st, 1926.

## THE TREATMENT OF SCIATICA

*To the Editor of* THE LANCET.

SIR,—Dr. J. P. Martin in his article in your issue of May 22nd on the treatment of sciatica does not include the local application of ultra-violet rays as one of the methods of treatment for this condition. The method is extremely simple, simpler than any of the methods mentioned, and is free from any danger of burns or shocks. The most convenient lamp for the purpose is the Kromayer (water-cooled mercury vapour) which is applied in contact with the skin. The applications are made over the nerve roots and along the course of the sciatic, giving one–two minutes (a third degree erythema, depending on the age of the lamp), particularly to points which are tender to pressure. Ten such points or more may be treated at one sitting, and others on succeeding days. Compared to galvanism, ionisation, or diathermy, it is much simpler, easier, and more rapid in its effects. One exposure to half-a-dozen areas has in some cases given considerable relief. This method has been used in chronic cases which have been treated by the older methods (including nerve stretching) without benefit for years, with striking results.

I confess it is difficult to find an explanation for the effect of ultra-violet treatment in these cases. It is extremely unlikely that any of the rays penetrate to the sciatic nerve, so any direct action must be excluded. Prof. Dixon has pointed out the similarity between ultra-violet rays and the mustard leaf in the effects on the skin (*Brit. Med. Jour.*, Sept. 19th, 1925). Counter-irritation alone, however, will not explain the results, for some of the cases still bore pigmented areas on their thighs as evidence of previous counter-irritants, which they stated had not given relief. Neither will a functional element serve as adequate explanation in the particular type of cases (pensioners) dealt with. The local analgesic action of ultra-violet rays will not explain the effect in chronic cases where the pain is probably due to adhesions and pressure on nerve-fibres within the sheath.

However, even though no adequate explanation can be given, we are no worse off theoretically than with most of the other methods, for there is no adequate explanation why ionisation, galvanism, or oxygen should give relief. The following are types of case which have been treated with benefit:—

CASE 1.—Admitted for treatment for bronchitis and asthma, but for the last two years had been complaining of a left-sided sciatica. In 1924 he was treated at an infirmary for seven weeks without benefit. He was at home in bed for four months and then treated at another hospital for several months. On admission here in November, 1925, he was walking with a crutch. He was complaining of pain across the loins and could not put his heel to the ground, owing to the pain it caused in the whole limb. Within a week he discarded his crutch, walking with the aid of a stick only, and he soon discarded that too. He was in the hospital for treatment for his bronchitis and asthma for two months. During this period the treatment for sciatica was continued, both local and general ultra-violet baths being given. By the end of the two months he had made up a half inch wasting of the thigh and his sciatica had disappeared.

CASE 2.—Contracted sciatica 1913. He had attacks at intervals till 1920, and since then he has been treated with radiant heat, massage, and electrical methods at one hospital or another every year. He was discharged from one hospital in March, 1925, but was readmitted to another in August. For two months he was on massage, radiant heat, and electrical treatment without benefit. When he came to the "Light" Department in October he was limping along with the help of a stick. He was tender to pressure along the course of the sciatic, and there was half inch wasting of thigh and calf. He also had a marked synovitis of the right knee. Within three weeks he discarded his stick and could walk three miles. Within two months the synovitis had disappeared, and also the wasting of the limb. He had gained 10 lb. weight and was discharged.

Not all cases will respond, but of ten cases, with an average history of seven years, there have only been two failures. One of these was on treatment for a short period, but as he was showing no signs of improvement, the nerve was stretched by the open method with considerable success, a previous manipulation having failed to give him relief. The other case also had the nerve stretched after a period of ultra-violet treatment without benefit. It should be added that all these cases were also given general ultra-violet radiation as a general tonic. I feel, however, that the effect was mainly due to the local treatment, as the symptoms disappeared in some of the cases before the general baths could have had an appreciable effect.

I am, Sir, yours faithfully,
M. WEINBREN.
The Queen's Hospital, Frognal, Sidcup, Kent,
June 2nd, 1926.

## FILIGREE IN HERNIA OPERATIONS.

*To the Editor of* THE LANCET.

SIR,—The article by Mr. Percival P. Cole in THE LANCET of May 22nd must compel attention to the use of the filigree in the operation for the radical cure of inguinal hernia. His figures are so convincing that they cannot be disregarded by those interested in the problems of hernia. They should silence once and for all the unfair criticisms levelled against the method in text-books of surgery and in monographs on hernia—criticisms not infrequently repeated by those who have not given the method a fair trial nor mastered the technique of the operation. Such results should embolden those who are restrained from the use of the filigree because of theoretical objections. Not uncommonly does theory mislead or misdirect us in the practice of surgery. It is regrettable that so simple, so effective, and so successful a method should not be more commonly practised.

The published results of hernia operations with their usual 6 to 8 per cent. recurrence in oblique inguinal hernia and very much larger, one might say appalling, recurrence rate in the direct variety are based on cases selected for operation after numbers have been rejected as unsuitable either *from* the point of view of age, size, type, or duration of hernia. Mr. Cole has drawn his series from the same source as that from which I quote cases below—viz., seamen, of whom none are refused operation. There is no selection. A hernia even controlled by truss prohibits a seaman from going to sea and therefore endangers his livelihood, so that operation cannot be refused. This fact adds immense weight to Mr. Cole's results as they stand, and in comparison with other reported series, and makes the filigree properly used almost indispensable in certain cases.

I find that in the last three years at the Seamen's Hospital—and I only quote these cases, although I have used the filigree elsewhere, and in my private work—that I have operated on 121 cases of hernia and in 28 have used filigrees. The filigrees were employed in recurrent inguinal hernia, direct inguinal hernia, and large oblique inguinal hernia of long standing in aged persons with but scanty musculature —cases, indeed, in which one has learnt by experience that high ligation of the sac alone or in combination with some form of plastic suturing would be insufficient. It is only natural that seamen would return to their hospital, which has a world-wide reputation amongst them for the treatment of hernia, if trouble followed the use of the filigree or if there were recurrence. In the last five years there has not been a single return for removal of the filigree for any cause, or for recurrence in a case where filigrees have been used.

I am, Sir, yours faithfully,

London, W., June 1st, 1926. E. T. C. MILLIGAN.

## LISTERISM IN MIDWIFERY.

*To the Editor of* THE LANCET.

SIR,—To the obituary notice of Sir John Williams in your last issue I should like just to add that he and I set up Listerian antiseptic midwifery at the General Lying-in Hospital in 1880—the first lying-in hospital in England to adopt Listerism. This is a piece of history which should not be lost.

I am, Sir, yours faithfully,

Uckfield, Sussex, June 4th, 1926. F. H. CHAMPNEYS.

## AUTOLYTIC PRODUCTS AND MALIGNANT TUMOURS.

*To the Editor of* THE LANCET.

SIR,—In Dr. Gye's communication to the Surgical Section of the Royal Society of Medicine, reported in your last issue, and also in his original paper on the origin of tumours, he fails to call attention to a fact which has been known for many years—viz., that the autolytic products of tumour tissue contain substances which are stimulating to the growth of tumour cells. These substances are certainly chemical bodies and not living agents, they act in high dilution, and they are in all probability end-cleavage products of enzyme action. We have reason to suppose that they are present in other tissues than malignant tumours, such as embryo tissue, mammary tissue, and placenta, in fact in all tissues rich in nuclear structures. Stimulation of growth with embryo tissues was obtained as long ago as 1910 by Haaland and others.

It is evidently of great importance in proving Dr. Gye's argument that the tests he has carried out on his control tubes containing autolysed embryo tissue are completely reliable. Dr. Murphy and he disagree on this point. When two entirely conscientious experimenters differ in the results they obtain with a particular group of experiments it usually means that both are recording true results, and I should hesitate to disbelieve Dr. Murphy's positive findings notwithstanding Dr. Gye's 150 experiments with negative findings. The explanation is, very probably, that some slight but important difference of technique has occurred. In test-tubes containing autolysing tissue the contents of the tubes are constantly changing and are changing in different degrees in different parts of the same tube. I should expect to find growth stimulants at the bottom of the tubes but not necessarily in the upper fluid. If one observer has stirred his tubes and the other has not, different results might easily be obtained. Dr. Gye acknowledges that his Rous virus may not be actually killed in the chloroformed extracts. It seems therefore that he is really studying the factors which can revive an attenuated Rous virus rather than the "origin of tumours."

Dr. Gye has undoubtedly done a great service to research and I do not question the facts he has observed, only the interpretation he has put upon them. To the researcher there is no problem more open to pitfalls or more difficult than the true interpretation of results.

I am, Sir, yours faithfully,

Watford, June 3rd, 1926. HELEN CHAMBERS.

## BIRTH INJURIES TO THE EYE.

*To the Editor of* THE LANCET.

SIR,—In your annotation with this title, published in THE LANCET of June 5th, you say, in referring to the corneal scars left after rupture of the posterior elastic lamina: "These scars are always vertical, or approximately so, a fact probably related to the direction of pressure by the forceps." You will, we feel sure, allow us to mention that this is not a strictly accurate statement. A reference to our article, Obstetric Injuries of the Cornea, in the *Ophthalmoscope* for 1905, and on p. 271, will show that out of ten cases there shown in diagram, the opacity was transverse in one and concentric with the corneal limbus in another. Further, on the supplement page which faces p. 207, there is an actual drawing of the transverse case. It is true that the scars are usually more or less vertical, but we are of opinion that they may occur in almost any direction.

We are, Sir, yours faithfully,

Stirling, June 8th, 1926. ERNEST THOMSON.
Glasgow, June 8th, 1926. LESLIE BUCHANAN.

---

**COMPLIMENTARY DINNER TO PROF. FIBIGER.**—The medical staff of the Cancer Hospital (Fulham-road, London) gave a dinner at the Langham Hotel on June 7th to Prof. Johannes Fibiger, of Copenhagen, in recognition of his eminent services to cancer research. The chair was taken by Mr. Ernest Miles, senior surgeon to the hospital, and among those present were Lord Dawson, Sir Humphry Rolleston, Sir John Bland-Sutton, Sir Frederick Andrewes, Sir Walter Fletcher, Profs. Muir, Bulloch, Dreyer, Dean, Ledingham, and Lazarus Barlow, Dr. H. H. Dale, Dr. W. E. Gye, Sir James Dundas-Grant, Mr. Cecil Rowntree, Mr. Percival Cole, Mr. Cecil Joll, Mr. C. E. Shattock, Dr. Stanley Wyard, Dr. H. Robinson, Dr. E. L. Kennaway, Dr. H. J. B. Fry, Dr. J. O. Harvey, Dr. J. E. A. Lynham, Dr. R. Knox, Dr. W. Cramer, Mr. L. A. Harwood, Dr. Archibald Leitch, and Mr. A. L. Abel.

**PROF. G. M. ROBERTSON ON LUNACY CERTIFICATION.** At a lecture given under the auspices of the Edinburgh branch of the British Medical Association on June 1st, Prof. Robertson stated that certification was essentially confidential and personal and that action might easily be taken against a doctor on a patient's release from an asylum or mental hospital, especially as with many patients the recovery was only partial. He urged the necessity of protection by some society. It was usually the second certifying doctor, who did not know the patient so well, who bore the brunt of the action. The provision of the Act was that "reasonable care" should be exercised; if a second visit was paid and careful notes taken, this should satisfy any jury with regard to necessary care. The word "lunatic" being a medico-legal term denoting a person suffering from disease of the mind affecting conduct, a person could not be deprived of liberty unless he was of unsound mind affecting his conduct with regard to the safety of himself or others. The best way out of any difficulty was to persuade the person to enter a mental hospital as a voluntary patient, and this was not so difficult as might be supposed; nowadays, in fact, in the higher paying hospitals, 60 to 80 per cent. entered on this basis, although unfortunately this was not the case to the same extent in parish-controlled hospitals where Government grant was lost unless a patient were certified.

# Obituary.

---

## SIR WILLIAM BOOG LEISHMAN, K.C.M.G., C.B., M.B., C.M. Glasg., F.R.C.P. Lond., F.R.S., LL.D.,

DIRECTOR-GENERAL, A.M.S.

Not only the medical profession but the whole scientific world learned with real grief the death last week, after a brief illness, of Sir William Leishman, Director-General of the Army Medical Service for the past three years. He belonged to a select and extraordinarily able band of men who during the first quarter of this century have revolutionised the whole outlook of tropical medicine, and within that band he specially distinguished himself by his large and independent researches, while contributing with untiring and unselfish effort to the general output.

Sir William Leishman.

William Boog Leishman was born in 1805, the son of Dr. William Leishman, professor of midwifery and obstetrics in the University of Glasgow. He was educated at Westminster School, and entered the medical profession as a student at his father's university, where he graduated M.B., C.M. in 1880. He joined the R.A.M.C. the following year, holding his first commission, therefore, at the age of 22. He proceeded on foreign duty in 1800, and first saw active service with the Waziristan expedition in 1801, where he obtained the medal and clasp. By this time he had already begun to take a close interest in bacteriology, especially in relation to the tropical diseases malaria and dysentery, with which he found himself in perpetual contact. On return to England in 1807 he was stationed at Netley, where he did duty in the wards, but spent all his spare time in the excellent laboratories of the Army Medical School under Sir Almroth Wright and Sir David Semple, then respectively professor and assistant professor of pathology. During this period he assisted Wright in the early work on typhoid vaccine and made some investigations into Malta fever, a disease which later he contracted himself in the laboratory. He also took part in the teaching and demonstrating in the classes for surgeons on probation, and did this so well and showed such aptitude that he was appointed assistant professor in 1000 when Semple went to India. We learn from Sir Almroth Wright that on his arrival at Netley it was significant that he seemed not to know his own splendid capacities for research. Wright had launched between the years 1807 and 1000 his great antityphoid work, and was proceeding with researches in vaccine therapy. These were impeded because the bactericidal power of the serum did not give the necessary indications, and Leishman invented the method of testing the phagocytic power in vitro with resulting developments. At that time at Netley leucocytes were being stained by the cumbrous method which goes by the name of Romanovsky, and Leishman introduced his stain, which has now quite superseded its predecessor. Romanovsky had used mixed solutions of methylene-blue and eosin, and Leishman had the inspiration to mix these together to filter off the precipitate and to dissolve it in methyl alcohol, a solvent used by Jenner in making his stain. These things are mentioned to show how well there were combined in Leishman the ability to devise and acquire technique with the large views later to result in great ends.

At Netley, while still associated with Wright, the beginning was made of the discoveries which led to Leishman's early recognition as a pioneer in tropical medicine. He showed Wright some preparations which he had stained and which had been taken from the spleen after a post-mortem on a man who had died of "dum dum fever," as it was then called. The whole field of the microscope was thickly sown with small oval bodies corresponding with nothing that Wright or he had ever seen or read of—what are now known as *leishmania* parasites—and Leishman, who was a most excellent artist, made some drawings and kept the matter in his mind. Later, when the Royal Army Medical School had moved to London, the work being done at what was then the laboratory of the Conjoint Board, Leishman noticed formed elements when looking at specimens derived from animals who had died with the trypanosomes recently discovered by Bruce and found in rats infected with nagana. These put him in mind of the organisms which had completely puzzled both him and Wright, and he worked on the theory that the organisms which he had previously observed were stages in the life-history of a protozoon, a view which was later confirmed in Calcutta by Rogers, who proved that these bodies, when introduced into a suitable medium, are converted into a flagellate resembling the trypanosome, thus substantiating Leishman's original view of the parasite.

That Leishman was not the first to see the parasites is now admitted. Cunningham, in 1885, described peculiar parasitic organisms in "Delhi boil," and considered that the bodies were a form of spore. In 1801 Firth appears to have seen similar bodies, but thought they were sporozoa. After Leishman's discovery, speculations were rife as to the nature of the bodies; Laveran and Mesnil suggested that they were piroplasma, but Ross, like Firth, thought that they were sporozoa, and afforded them the dignity of genus by the title of "leishmania." This adaptation of Leishman's name has, in time, come to be applied to the whole group of diseases now known as "leishmaniasis." In 1003 Donovan in India recorded parasites similar to those described by Leishman in the tissue of patients dying of kala-azar, after which the organism, therefore, came to be known as the Leishman-Donovan body. And in the same year J. H. Wright, confirming Cunningham, saw bodies in an oriental sore which later became known as the parasite of oriental sore, or "Delhi boil" as it is sometimes called, and has been scientifically termed "Leishmania tropica." In 1004 came Rogers's substantiation of Leishman's original view as to the parasite. The group of diseases is now much expanded. Similar parasites were found in sores in Brazil by Lindenburg, Carini, and Paranhos in 1000; Splendore and Carini showed that the peculiar ulceration of the pharynx and nares in South America, commonly known as bubas, was also leishmaniasis. It is now known that kala-azar has almost a world-wide distribution; it has been found in Central Africa and Northern China, while a similar disease is very common in the Aegean Islands and the Mediterranean area, where it attacks both children and dogs. The disease group which bears Leishman's name is, therefore, of high economic importance, as one of the most widespread scourges which afflict mankind.

From 1905 onwards Leishman devoted much of his time to the observation of pathogenic spirochætes, especially *Treponema pallidum* and the allied parasites of yaws and relapsing fever. His early investigations were concerned with the morphology of these spirochætes and the relation which might exist between European and African forms, but he found it was impossible to substantiate any morphological differences. He expended great labour in attempting to cultivate these organisms in artificial media, and observed in so doing the peculiar agglutination of the spirochæte. His experiments were afterwards directed towards the changes undergone by the spirochætes in the tick's body, and the manner in which hereditary transmission takes place in the arthropod. He found it impossible to trace the spirochætes in the body of a tick later than the tenth day after feeding, and his researches on the eggs laid by infected ticks were negative. While these experiments were in progress he was struck by the frequent occurrence of clumps of granules in various parts of the tick's body which he suspected as being of parasitic nature, and which he continued to regard as stages of the development of the spirochæte; and later, when the advantage of the dark-ground illumination method came in he was able to satisfy himself that young spirochætes actually developed from these granules. His researches on this subject were made the subject of a summary in the Horace Dobell lecture delivered before the Royal College of Physicians of London in 1920. Much of this work has been confirmed by Nicolle and his colleagues in their observations upon the development of the spirochæte in the louse, in which gradually the organisms appear to undergo a life-history similar to that described by Leishman.

To go back in the tale, in 1903 Leishman succeeded Wright as Professor of Pathology in the Royal Army Medical College when, in addition to discharging the arduous duties of the post with the spirit which bore splendid fruit during the whole ten years of his office, he carried out a scheme in respect of antityphoid inoculation which had been already devised by Wright and himself. This was to inoculate a series of groups of men with different doses of typhoid vaccine, afterwards measuring their immunisation curves with a view to selecting the optimum dose of vaccine, which was thus fixed at 1000 millions for the first dose. The work which Leishman did in the introduction of vaccine and inoculation against typhoid fever constitutes his most important contribution to medicine, far-reaching as the other discoveries have been or may be. This method had already been tried during the South African War, but the reaction that it produced, and the ill-health which resulted from the inoculation as then prepared, was too severe, allowing a certain class of critic to insist that the cure was worse than the disease. But from 1902 onwards, Leishman, in association with Wright, busied himself in the preparation of a less potent preparation. The early experiments were summarised in the Harben lecture for 1910, and published in the *Journal* of the Royal Institute of Public Health and are familiar to all. The original ravages of enteric fever in India amongst the British garrisons, where it was especially prevalent, were taken into account as well as the lessons of the South African War, when there were no less than 57,000 cases of enteric fever with over 8000 deaths. To the subsequent intensive study we owe the preparation of the typhoid vaccine which was used with such success in the recent war, a success mainly lying in the observations of the growth of the organism and in the details of the technique of sterilisation. The result achieved is now universally recognised and the lessons have been published widely. They were well set out by Leishman himself in a paper entitled "Enteric Fevers in the British Expeditionary Force of 1914–1918" and published in the *Glasgow Medical Journal* in 1921. From this paper we learn that he first decided that the best protection could be obtained by the initial test of 500 million organisms, followed a week or so later by one double that amount. The immediate returns appeared to be unfavourable to the continuance of this method, but it was ascertained that the increase of cases was due to the paratyphoid organisms, and when these were added to the vaccine almost complete protection was produced—a striking vindication of Leishman's work. As the result of the inoculation of the vaccine there was secured for our men a considerable measure of protection against the paratyphoid infection as well as against typhoid, though the immunity produced against the former was not of such a high degree as against the latter. We may quote the remarkable figures. In 115, in the strength of over 600,000 troops there were only 570 cases of enteric fever notified with 34 deaths; a striking comparison with the figures of 14 years previously in South Africa.

While all this original work was in process Leishman was winning a wonderful name for himself, for he developed powers of teaching which a large number of officers can testify proved to be of the highest value to them. Many we know would speak with real gratitude of the good derived from his instruction and guidance. He was a most patient and painstaking instructor—nothing here seemed a trouble to him that would assist in explaining a point or clearing up a difficulty; he was an able and even brilliant lecturer, and it is no wonder that his work should have borne the fruit that it did.

At the outbreak of war Leishman, officially described as Expert in Tropical Diseases on the Army Medical Advisory Board, was directed to join the Expeditionary Force on Oct. 3rd, 1914, and was attached in an advisory capacity to the staff of the D.M.S. of the Force. A few months later the designation of "Adviser in Pathology" was attached to the post. The following list will give some idea of the different lines of work which had devolved on him by the year 1917: 1. Adviser in pathology to the Expeditionary Force. 2. Member of the Advisory Board of the Director-General, Medical Services, G.H.Q. 3. Chairman of research committees on trench fever and on nephritis. 4. Inspection of all mobile and hospital laboratories, at the front and on the lines of communication. 5. Coördination of the work done in the laboratories. 6. Recommendations on appointments to the charge of laboratories. 7. Advice on the installation and equipment of new laboratories. 8. Distribution of laboratories and pathologists to meet local emergencies. 9. Advice to medical store department on laboratory equipment, reagents, apparatus, &c. 10. Advice on all matters relating to the supply and employment of sera and vaccines. 11. Advice on tropical and parasitic diseases in native troops and labour contingents. 12. Collaboration with the A.D.M.S. (Sanitation) in the control of infectious disease. 13. Collection and analysis of returns relating to enteric fever and tetanus. 14. Reports to the D.G.M.S., G.H.Q., and to the D.G.A.M.S., War Office. 15. Arrangements for the collection of pathological specimens. 16. Member of the Inter-Allied Sanitary Commission, Paris. 17. Member of the Inter-Allied Surgical Conference, Paris. 18. Liaison with the pathological work of the armies of the Allies. Even this list is not exhaustive; it is set out to show the multifarious and important responsibilities which had accrued to him by the time the critical later stages of the war were reached; that he should have fulfilled them satisfactorily makes a splendid record of service, and that he should have been instructed to undertake them proves what the estimate of him was in the highest places.

When the Directorates of Pathology and Hygiene were formed at the War Office in 1919, Sir William Leishman was appointed Director of Pathology and remained in that appointment until 1923. During those four years his activities were far-reaching, and his work established the newly formed directorate on a solid and enduring foundation. His advice and support to the then Director-General on matters concerned with pathological science were of extreme value, as Sir John Goodwin has testified, both to his official chief and to the Army generally. In 1923 he was appointed to be Director-General of Army Medical Services at the War Office, an onerous post, the duties of which he was performing with the greatest distinction and ability when he was cut off in the midst of his work, and just when so many of the problems and projects in which he was engaged bore promise of ampler fruition. While many regretted the necessary break constituted in a brilliant scientific career by the call to become Director-General, there were at least as many who recognised that Leishman's right to be the head of the Service was so incontestable that any other appointment would have been open to criticism, while it was certain that he would bring to that position the qualities which he had already displayed in scientific and official fields, to the great benefit of an organisation to which he was devoted.

Outside the Army Medical Service Leishman's appointments and responsibilities were also great and various. He was a member of the Yellow Fever Commission, West Africa (1913–15), and of the Medical and Sanitary Advisory Committee for Tropical Africa at the Colonial Office; he was for ten years a member of the Medical Research Council, vacating his seat on appointment as Director-General; he was a member of the Scientific Advisory Committee of the British Empire Cancer Campaign, quite recently he was appointed chairman of the Foot-and-Mouth Disease Research Committee of the Ministry of Agriculture; he was a past President of the Society of Tropical Medicine and Hygiene and had acted as examiner in pathology at Oxford and in tropical medicine at Cambridge. Just before his death he was elected President of the Section of Comparative Medicine at the Royal Society of Medicine, an appointment which shows alike that the wide range of his learning was appreciated by colleagues, and that his own desire was keen to remain actively associated with scientific work as far as the duties of his high official post would permit him to do so. His contributions to medical and scientific literature were numerous and particularly instructive as being personal records. These papers will be found in THE LANCET, *British Medical Journal*, the *Journal of Tropical Medicine and Hygiene*, the *Journal of the Royal Army Medical Corps*, the *Glasgow Medical Journal*, the *Journal of the Royal Institute of Public Health*, as well as in the Transactions of the Royal Society, while he also wrote the article on kala-azar in Allbutt and Rolleston's "System of Medicine"

In 1910 Leishman was elected a Fellow of the Royal Society, and served for two years as Vice-President. He was knighted in 1909, and in 1912, having just been promoted Colonel, he was appointed honorary physician to the King. He was created C.B. in 1915, K.C.M.G. in 1918, and K.C.B. in 1921, and was continually mentioned in dispatches during the European War; he was a Companion of the Legion of Honour and held the Distinguished Service Medal of the United States Army.

The story thus set out indicates a life that was lived to the extreme limits of intellectual ability and physical capacity, but it remains to add that the brilliant researcher and competent official was the simplest of men, transacting his duties with no evidence of strain and bearing his honours without a trace of manner. As far as possible, he seemed to efface himself, his courtesy was clearly genuine, his personal kindness can be testified to by a large series of contemporaries and juniors, and his generosity to fellow workers was unfailing. His premature death after a brief illness was a real grief to friends, colleagues, and a big and various public.

Sir William Leishman married, in 1902, Maud, eldest daughter of the late Colonel E. Gunter, by whom he had one son and three daughters, to whom all sympathy in their loss will be extended. The funeral service was held in the Chapel at the Military Hospital, Millbank, conducted by the Rev. A. C. E. Jarvis, Chaplain-General to the Forces, assisted by the Rev. C. Thacker, Chaplain to the Hospital, and the Rev. P. McCormick, the Westminster Abbey choir attending. The King and the Queen were represented at the impressive service, as were the numerous public bodies in whose conduct Sir William Leishman had played so prominent a part. The pall-bearers were drawn from the heads of the medical services of the Navy, Army, and Air Force, and a guard of honour with regimental band was provided by the Grenadier Guards, the route being also lined by officers of the R.A.M.C. and nursing sisters. The funeral was conducted privately at Highgate.

## SIR STEWART STOCKMAN, M.R.C.V.S.

BY the death of Sir Stewart Stockman veterinary science has suffered a severe loss. His name will be permanently associated with the courageous stand to eradicate from this country the menace of foot-and-mouth disease. He had the strength of character to press his professional convictions into effective execution in spite of much adverse clamour, and in so doing gained the confidence of the Government department he served, of the veterinary profession, and, still more important, of the farming community which came to regard him as a wise and trusted counsellor.

Born in 1869, the fourth son of the late Mr. W. J. Stockman, merchant, of Edinburgh and Leith, he received his early education at the Edinburgh High School and his veterinary training at the Royal (Dick) Veterinary College, Edinburgh, from which he qualified as member of the Royal College of Veterinary Surgeons in 1890. Subsequently he studied abroad, chiefly at the École Nationale Vétérinaire, Alfort, Paris, and then occupied the posts successively of demonstrator of pathology and professor of pathology at the Royal (Dick) Veterinary College, Edinburgh. In the course of these years he came into intimate contact with the masters of comparative pathology—Nocard, in France, and McFadyean, in England. He resigned his teaching appointment in 1900 to serve in the South African War, and after the termination of the war accepted a post in the Indian Civil Veterinary Department. He was among the first batch of civilian veterinary surgeons to occupy posts in this department, and his stay in India—an ideal training-ground for the epizoologist—though brief, gave him opportunity to demonstrate his capacities; his work on cattle plague (rinderpest) ranks as a real contribution to knowledge among a mass of misleading information based on faulty field observation. He was then selected for appointment as principal veterinary officer to the Transvaal, in which capacity he served for three years. His South African experience, though again short, was eventful. In 1896 cattle plague had spread southwards, causing terrible havoc among the cattle population of South Africa and depriving the inhabitants of their main means of support. Later alarming new epizoötics appeared, notably the piroplasmoses ("redwater") and East Coast fever. With the brilliant collaboration of Sir Arnold Theiler, then veterinary research officer to the Transvaal, the rationale of control was elucidated, and Stockman realised its execution by introducing a system of veterinary police control which still remains

In 1905 Stockman was appointed chief veterinary officer to the Board (now the Ministry) of Agriculture and Fisheries, to administer the Diseases of Animals Acts At the time of his appointment there was hardly any research work executed by the veterinary department of the Board. Stockman's activities lay in two directions—first, in the organisation of a field service composed wholly of qualified men, and, secondly, in the establishment of a properly staffed and equipped research section. With the hearty support of Mr. Walter Runciman there was erected, near Weybridge, a first-class laboratory—the first institute in the United Kingdom for research into prevalent animal diseases. Under the able direction of Stockman, who was appointed director of veterinary research to the Ministry, a series of valuable researches was carried out, all with direct bearing upon the problems of animal husbandry. Even before adequate laboratory facilities were forthcoming a piece of work on bovine epizoötic abortion was performed in collaboration with Sir John McFadyean. Since then "redwater" and other diseases of cattle, scrapie and louping-ill of sheep, swine fever, certain diseases of poultry have been studied, and, at the present time, experimental work upon a large scale is being carried out upon the nature of the foot-and-mouth virus.

Although in the course of his lifetime Stockman attained international repute as an experimentalist and a shrewd and conservative observer in researches into animal disease it is as an epizoölogist, a veterinary Gorgas, that he will chiefly be remembered. He worked without ceasing to free British livestock from the incursions of contagious disease, and succeeded to a degree unknown in other countries; witness the work done under his direction to suppress rabies, to eliminate glanders, to mitigate the ravages of swine fever by means acceptable to the agriculturist, and to bring about the dwindling incidence of sheep scab. His efforts to prevent foot-and-mouth disease from becoming an ever-imminent danger to the existence of our herds told heavily upon his physical health in recent years. He had just returned from a tour in the Argentine, undertaken for the purpose of investigating there the conditions of the meat trade with this country. The state of his health prevented taking up further duties on his return, and he journeyed to Glasgow to obtain advice and treatment from his brother, Prof. Ralph Stockman. He died suddenly on June 2nd and was buried at Warriston Cemetery, Edinburgh.

Stockman was joint editor of the *Journal of Comparative Pathology and Therapeutics*, a member of the Council of the Royal College of Veterinary Surgeons, President of the Royal College of Veterinary Surgeons for the year 1924–25, a former member of the Council of the Royal Society of Tropical Medicine and Hygiene, member of the managing committees of the Tropical Diseases Bureau and Imperial Bureau of Entomology, and a member of the Board of Governors of the Royal Veterinary College, London. He had edited Walley's "Meat Inspection," among other publications. He received the honour of knighthood in 1913. He married in 1908 Ethel, elder daughter of Sir John McFadyean, and leaves a widow and two daughters.

---

THE LATE DR. W. HOOD.—Dr. William Hood, who died at York on May 27th at the age of 88, had an unusually interesting life. He was born at York, the son of a wine merchant, and was educated at St. Peter's School. As a lad he served as apprentice to a doctor in St. Leonards before going to St. Bartholomew's Hospital, and after qualifying as M.R.C.S. Eng. in 1860 and as L.S.A. in 1861, went back for a time to York as an assistant. Then he became surgeon in the Royal West India Mail Service and worked on the paddle boats running between Mexico and Panama. From this time onwards he travelled much, and at the age of 73 set out alone on a tour of Russia and Finland. Crossing Russia with the idea of getting through to Persia he was held up on the frontier, but succeeded in reaching Baku and made his way home by way of Vienna. A year later he went round the world, also unaccompanied, and his robust health is shown by the fact that until two years ago he enjoyed bicycling. Dr. Hood settled in practice at York in 1863 and married Miss Frances Lockwood, a cousin of the late Sir Frank Lockwood, M.P. He became medical officer to the York Union and served the city in that capacity and as public vaccinator for nearly 50 years, retiring in 1911. He was a keen collector of antiques, and especially of old prints. Dr. Hood's wife died in 1910; he leaves a daughter and four sons, one of whom is a member of the medical profession.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

*Honours.*—Kathleen M. Bowman-Manifold (*a*, *b*), London Sch. of Med. for Women; Robert B. Brew (*b*), Univ. Coll. Hosp.; Anacletus Byrne-Quinn (*d*), St. Thomas's Hosp.; Joseph T. Fathi (*d*), London Hosp.; Margaret A. Harrison (*a*) and Marjorie Low (*a*), London Sch. of Med. for Women; Mary C. Luff (*b*), Univ. Coll. Hosp.; William A. Mill (*d*), Guy's Hosp.; Joseph Shepherd (*a*), Univ. Coll. Hosp.; Hyman Simmonds (*d*), St. Bart.'s Hosp.; J. H. Simmons (*a*), King's Coll. Hosp.; Jean L. Smith (*a*), Charing Cross Hosp.; Dorothy E. Stewart (*e*), London Sch. of Med. for Women; and Robert M. Walker (*d*, *e*, University medal), Univ. Coll. Hosp.

(*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology.
(*d*) Distinguished in Surgery. (*e*) Distinguished in Midwifery.

*Pass.*—Russel C. Amies, St. Thomas's Hosp.; Constance E. Appleton, King's Coll. Hosp.; Edgar C. Archer, St. Thomas's Hosp.; Edward Bacon and Roderick T. Bannister, St. Bart.'s Hosp.; James M. Barnard, Charing Cross Hosp.; Cyril E. Beare, Middlesex Hosp.; Harold C. Beccle, Guy's Hosp.; John G. Y. Bell, King's Coll. Hosp.; Judah S. Benzecry, Univ. Coll. Hosp.; Samuel Berman, Guy's Hosp.; Frank A. Bevan, St. Bart.'s Hosp.; Owen P. Bowers, St. George's Hosp.; Margery G. Blackie, London Sch. of Med. for Women; John R. Blazé, Ceylon Med. Coll. and Univ. Coll. Hosp.; Anna M. V. Bonhote, King's Coll. Hosp.; Harry C. Boyde, St. Bart.'s Hosp.; Lucy Burnett and Olive K. Burnett, London Sch. of Med. for Women; Laurence W. Cann, Guy's Hosp.; Elizabeth J. Carpenter, London Sch. of Med. for Women; Walter S. Chapman, Univ. Coll. Hosp.; Francis W. Charman, King's Coll. Hosp.; Enid Clarke, London Sch. of Med. for Women; Violet H. Comber, Univ. Coll. Hosp.; Louis N. R. Comty, London Hosp.; Victoria M. Crosse, London Sch. of Med. for Women; Evelyn J. Curtis, King's Coll. Hosp.; Philip E. J. Cutting, St. Bart.'s Hosp.; Gweneth M. Daniel, Westminster Hosp.; David J. Davies, Middlesex Hosp.; Thomas D. Deighton, St. Bart.'s Hosp.; Mathew De Lacey, London Hosp.; Alma Downes-Shaw, King's Coll. Hosp.; George E. Ellis, St. Bart.'s Hosp.; Harry G. Estcourt, Middlesex Hosp.; William G. Evans, St. Mary's Hosp.; Christabel S. Eyre, Charing Cross Hosp.; Rachel D. Fox, London Sch. of Med. for Women; Duncan B. Fraser, St. Bart.'s Hosp.; Ernest B. Garrett, Univ. Coll. Hosp.; Winefride M. Gibson, Charing Cross Hosp.; John F. E. Gillam, St. Thomas's Hosp.; Edith L. Gould and Agnes H. S. Gray, London Sch. of Med. for Women; Francis H. K. Green, St. Bart.'s Hosp.; Charles S. Hallpike, Guy's Hosp.; Helen M. Harris and Leila M. Hawksley, London Sch. of Med. for Women; Thomas R. Hill, Guy's Hosp.; Katherine M. Hirst, London Sch. of Med. for Women; Janet K. Holgate, Univ. Coll. Hosp.; Ruth T. Hurnard, London Sch. of Med. for Women; Kenneth M. N. Isaacs, London Hosp.; Arthur D. W. Jones, Westminster Hosp.; Ronald H. Knight, St. Bart.'s Hosp.; Geoffrey L. S. Kohnstam, King's Coll. Hosp.; Mary Langdon-Down, London Sch. of Med. for Women; Nora M. Leesmith, St. Mary's Hosp.; Samuel Lerner, Univ. Coll. Hosp.; Lewis O. Lindsay, London Hosp.; Dorothy M. Llewellin, Westminster Hosp.; Kathleen M. Lyons and Duncan C. McIntosh, Univ. Coll. Hosp.; James H. Macpherson, King's Coll. Hosp.; Joan G. Malleson, Charing Cross Hosp.; Eva M. Malmberg, King's Coll. Hosp.; George R. Marcano, St. Thomas's Hosp.; Frank Marsh, Guy's Hosp.; Derrick J. Martin, London Hosp.; Florence I. J. Masterman and Dorothy G. Medway, London Sch. of Med. for Women; Alfred Mitchell, King's Coll. Hosp.; John P. Monkhouse, St. Mary's Hosp.; Mary A. Monro and Florence I. R. Moore, London Sch. of Med. for Women; George S. Morgan, St. Bart.'s Hosp.; Gwyn J. Morris, Middlesex Hosp.; Norman Moulson, St. Bart.'s Hosp.; Margaret I. Neal, London Hosp.; Grace H. Nicolle, London Sch.. of Med. for Women and St. Mary's Hosp.; Gwynedd Mary E. Olive, London Sch. of Med. for Women; John O. Oliver, St. Thomas's Hosp.; John Parrish, St. Bart.'s Hosp.; Howard L. Peake, Guy's Hosp.; John Pearce, Westminster Hosp.; Noël R. Pooler, St. Mary's Hosp.; Dorothy F. Pratt, London Sch. of Med. for Women; Leslie Reuvid, Univ. Coll. Hosp.; Gordon H. Roberts, Charing Cross Hosp.; Victoria A. Roberts, London Sch. of Med. for Women; Allan B. Robinson, St. Thomas's Hosp.; May E. Rogers, London Sch. of Med. for Women; Harold N. Rose, St. Bart.'s Hosp.; Annie E. G. Rowlands, Univ. Coll. Hosp.; Marjorie Rushbrooke, University of Birmingham; Doris M. F. Russell, London Sch. of Med. for Women; Alan R. Rutnam, Middlesex Hosp.; Joseph Ryland-Whitaker, University of Edinburgh; Frederick W. Schofield, Guy's Hosp.; Thomas A. Seekings, Univ. Coll. Hosp.; Constance G. Sloan, St. Mary's Hosp.; Leonard Smalley, St. Thomas's Hosp.; Rachel M. S. Smellie, St. Mary's Hosp.; Beatrice G. Smith, Univ. Coll. Hosp.; Ralph Stanford, London Hosp.; Adrian L. Stephen and Ian H. Stevens, Univ. Coll. Hosp.; Frederick O. T. Strange, King's Coll. Hosp.; Basil R. Sworn, St. Thomas's Hosp.; Josephine I. Terry, St. Mary's Hosp.; Basil M. Hosp.; Janet Welch, London Sch. of Med. for Women; Harry V. Wells, Charing Cross

Hosp.; William S. Whimster, Guy's Hosp.; Dahlia Whitbourne, Gwendolen L. Wilkins, and Katharine G. L. Williams, London Sch. of Med. for Women; Ada R. Winter and Dorothy E. Wright, Univ. Coll. Hosp.; and John C. Young, Guy's Hosp.

University of London Club.—A reception will be held by the chairman, Dr Walter Seton, and members of the committee of the club, at the Club House, 21, Gower-street, London, W.C., on Tuesday, June 22nd, from 8.30 to 11.30 P.M., to meet the Vice-Chancellor, Prof. Ernest Gardner, and the members of the Senate.

Indian Medical Service Dinner Fund.—The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 16th. Lieut.-Colonel R. H. Elliot will take the chair. Tickets and all particulars may be had from the joint hon. secretary, Colonel J. J. Pratt, 18, Nevern Mansion, Warwick road, London, S.W. 5.

The late Prof. Babák.—Edward Babák, professor of physiology in the Masaryk University and Veterinary College in Brno, Czecho-Slovakia, died suddenly on May 29th, at the age of 53. His researches on the regulation of the respiratory movements are well known and his work on the influence of the endocrine glands on the metamorphosis of amphibia is no less important. His last published work is a book on the Biology of the Child. He was a remarkable teacher and built up a considerable school of physiology. Until 1918, when he was entrusted by the Government with the organisation of the Masaryk University and Veterinary College in Brno, he held the post of professor of physiology at the Charles University of Prague. Prof. Babák was the founder of the Biological Society of Czecho-Slovakia and of the journal *Biologicke Listy*.

Royal College of Surgeons of England: *Jacksonian Prize.*—The subject for this prize for 1926 is the Pathology, Diagnosis, and Treatment of Abscess of the Brain. The subject for 1927 is the Pathology, Diagnosis, and Treatment of Bronchiectasis and Abscess of the Lung. The dissertations for the prize for either year must be delivered at the College not later than Dec. 31st of that year.

*Cartwright Prize.*—The administration of the fund for this prize, founded by the "Association of Surgeons practising Dental Surgery" with the object of commemorating the services of Samuel Cartwright, F.R.C.S., in improving the status of the dental profession, has been entrusted to the Royal College of Surgeons of England, and the prize is now offered for competition under the following conditions. It will be awarded quinquennially, the next award being for the five years ending Dec. 31st, 1930. The prize consists of a medal executed in bronze and an honorarium of £35. The subject for the essays to be submitted in competition for the prize is the Ætiology, Pathology, and Treatment of Chronic General Periodontitis (Pyorrhœa Alveolaris). Candidates must be persons engaged in the study or practice of dental surgery and possessing qualifications capable of registration under the Medical Acts of the United Kingdom. Further particulars as to both these prizes may be obtained from the Secretary at the College.

Fellowship of Medicine and Post-Graduate Medical Association.—Two clinical demonstrations will be held on June 16th. At 12 noon Mr. Greeves will give a demonstration in Ophthalmology at the Royal London Ophthalmic Hospital, City-road, E.C., and at 2 P.M. Mr. Sidney Boyd will hold a surgical one at the Hampstead General Hospital, Haverstock Hill, N.W. From July 5th to 17th the National Hospital for Diseases of the Heart will hold an intensive course. Beginning on the same date there will be an afternoon course at the Hospital for Diseases of the Skin, Blackfriars. Instruction will be given in the out-patient department, and venereal clinics will be held bi-weekly. Special attention is drawn to the one week's special course in obstetrics which the City of London Maternity Hospital hopes to begin on July 5th, of which further details will be announced later. There will be a fortnight's special course of demonstrations at the Royal Eye Hospital from July 12th to 24th, from 3 P.M. onwards. All the members of the staff of the hospital will participate in these and will demonstrate on the various aspects of diseases of the eye. There will be an intensive course at the Prince of Wales's General Hospital, Tottenham, N., from July 10th to 31st, in medicine, surgery, and the specialties. Clinics will be held throughout the day in the various departments of the hospital and there will also be demonstrations in Fevers and Mental Diseases. From July 19th to August 14th the West End Hospital for Nervous Diseases will hold a late afternoon course (from 5 o'clock) in Neurology. Copies of all syllabuses, of the General Course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship of Medicine, at 1, Wimpole-street, London, W.1.

Royal College of Physicians, Edinburgh.—The George Alexander Gibson Memorial lecture on the Failing Heart will be delivered in the hall of the College on June 23rd and 24th, beginning each day at 5 P.M., by Dr. John Cowan.

Dr. Gerhard Hotz, professor of surgery at the University of Basle and director of the Surgical Clinic, died on June 5th of a perforated gastric ulcer, in his forty-sixth year.

London (R.F.H.) School of Medicine for Women.—On June 25th, at 3.30 P.M., Sir John Ferguson will present prizes and certificates. Lady Barrett, Dean of the School, will be in the chair.

A new solarium in connexion with the Tuberculosis Dispensary, 105, Grange-road, Bermondsey, will be opened on June 12th, at 3 P.M., by the Mayor of Bermondsey (Councillor I. Stokes). An address on Sunlight and Open Air will be given by Dr. Leonard Hill, F.R.S.

The Cripple Problem.—Sir Robert Jones, Emeritus President of the British Orthopædic Association, will give an address, for the Essex County Council, on the Cripple Problem, at River Plate House, 7–9, Finsbury-circus, London, E.C., at 3 P.M., on Friday, June 18th.

Dr. Norman Tattersall, who has been for the past 14 years tuberculosis physician for the Mid-Glamorgan area of the Welsh National Memorial Association, has been appointed tuberculosis physician to the City of Leeds. On May 22nd, at Bridgend, Glamorgan, he was the guest of a number of his medical friends at a dinner at which a bureau and illuminated address were presented to him.

A Windfall for Dublin Hospitals.—By his will the late Mr. William Dobbs McDonnell, of Shankill, Co. Dublin, who died on March 24th, bequeathed the residue of his estate, subject to certain legacies, to three Dublin hospitals. The question as to which of the Dublin hospitals should benefit was left to the President of the Royal College of Surgeons, Mr. R. C. B. Maunsell. Mr. Maunsell has now decided that the residue of the estate, amounting to about £10,000, is to be divided equally between Sir Patrick Dun's Hospital, Mercer's Hospital, and the Royal Hospital for Incurables.

Ross Institute for Tropical Diseases.—The Prince of Wales will on July 15th formally open the Ross Institute and Hospital for Tropical Diseases at Tibbett's Corner, Putney Heath. The Institute has been founded to commemorate the twenty-fifth anniversary of the discovery by Sir Ronald Ross of the transmission of malaria to human beings through the bite of the anopheline mosquito. It will be devoted to laboratory research and clinical investigation. Its objects are to carry on intensive research work in the prevention and treatment of tropical diseases, to assist medical men interested in such diseases to make researches, to receive in the hospital sufferers from tropical affections, and to create more interest in malaria and disease control work. Bath House, a large modern residence, has been bought and adapted at a cost of about £25,000, and the working expenses are estimated at from £8000 to £10,000 a year. The first patient was Sir Ronald Ross himself, a resident of Putney, who was taken ill in November last, but was able to leave in five days.

Royal Society of Medicine.—At the social evening held on June 7th Prof. Frederick Hobday gave a short address entitled "Our Animal Friends as Patients." He claimed that animals have the right to receive the best possible attention which modern veterinary skill can give them, and their owners should see that they receive it. He proceeded to consider under the headings of the various sections which compose the Royal Society of Medicine the question of veterinary in comparison with human treatment, and showed on the epidiascope cases in which the treatment of animals by modern medicine and surgery was almost identical with that given by the physician and surgeon to man. Attention was drawn to those common contagious diseases of domestic pets which were likely to infect man. Pictures were shown of the methods applied in the Royal Army Veterinary Corps during the war for the comfort of the horses and mules on each of the fronts. Referring to the intelligence, almost human, of horses and dogs, he gave detailed accounts of the experiences he had had with highly trained individual animals, showing that the reasoning powers of these creatures can be developed to a wonderful extent. The lecture was preceded by a conversazione, at which a large number of specimens were shown.

**RETIREMENT OF THE REGISTRAR-GENERAL OF THE IRISH FREE STATE.**—Sir William J. Thompson has just retired from the office of Registrar-General of the Irish Free State, having reached the limit of age. He was appointed to the office in 1909, having previously been a physician in Dublin and senior physician to Jerves-street Hospital. He had the chief responsibility for carrying out the census of 1911 and had much of the work of the preparation for the recent census. During his tenure of office he maintained the friendliest relations with medical men who were brought into touch with his department, and the profession in general regrets his retirement. It has been announced that the Government does not intend to fill the vacancy, but that in future the duties of the office will be performed by an official of the department of Local Government and Public Health.

**TUBERCULOSIS CONFERENCE.**—The twelfth annual conference of the National Association for the Prevention of Tuberculosis is to be held in Glasgow from Thursday to Saturday, July 1st to 3rd. The Lord Provost of Glasgow will formally open the conference at the McLellan Galleries, Sauchiehall-street, at 10.30 on Thursday morning, when the subject for discussion will be the Provision for the Care of Non-pulmonary Tuberculosis, to be opened by Dr. A. S. M. MacGregor, M.O.H. Glasgow, and Mr. James Taylor, consulting surgeon to the Glasgow Corporation Hospitals and Sanatoria. In the afternoon Sir Robert Philip will open a discussion on the Actual Place and Function of the Tuberculosis Dispensary in the Tuberculosis Scheme. A formal reception by the Lord Provost and magistrates will be held at 7.30 P.M. On Friday papers will be read as follow: on Experimental Studies in Tuberculosis, by Prof. C. H. Browning; on the Age-Factor in the Incidence of Tuberculosis, by Dr. J. A. Wilson; on Some Experiences in the Treatment of Tuberculosis by Artificial Sunlight, by Dr. Alexander Smith; and on Glasgow's Solution of the Smoke Problem, by ex-Bailie W. Brownhill Smith. On Friday afternoon visits will be paid to Corporation housing schemes and sanatoria and to the Hairmyres Tuberculosis Colony. On Saturday demonstrations will be given on radiography of the chest, the methods of treatment of non-pulmonary tuberculosis, and visits paid to various dispensaries and sanatoria. Further information from the Secretary of the National Association, 20, Hanover-square, London, W. 1.

**PRESENTATION TO DR. HERBERT JONES.**—Dr. Gerard Steel, President of the Herefordshire Medical Society, accompanied by Dr. John Steed, hon. treasurer of the society, and Dr. J. R. Bulman, hon. secretary of the Hereford Division of the B.M.A., recently presented a testimonial to Dr. Herbert Jones which took the form of a Sheffield plate casket, suitably inscribed, and containing a cheque for £250; it was accompanied by a list of the names of the subscribers. Dr. Steel referred to the privilege and honour conferred upon him in that it fell to his lot to present the casket and its contents as a token of the esteem in which he (Dr. Herbert Jones) was held by the whole profession. He then read extracts from letters which had been received from subscribers to the testimonial and continued: "You must feel great satisfaction in hearing these many expressions of gratitude for the good work you have done. They are a certain proof that the whole of your professional life is approved and acknowledged by your confrères, who sincerely wish you the peace and comfort in your retirement which you so richly deserve. At the same time they hope that you will always be available for them to ask for your help in all cases of difficulty when your ripe knowledge, experience, and judgment will be invaluable, as has ever been the case, for you have never failed in your integrity to your professional brethren by your tact and kindness to one and all." Dr. Herbert Jones thanked everyone who had helped in the testimonial. The work had ever been a labour of love. In glancing through the names on the list of subscribers he was much touched to notice not only the names of many old friends, but of several men who were scarcely known to him.

The following is the final list of subscribers:—

*£10 10s.*—*West of England Branch of the Soc. of M.O.H.; Midland Branch of the Soc. of M.O.H. (per Dr. Ridley Bailey).

*£3 3s.*—†Sir William H. Willcox, K.C.I.E.

*£2 2s. 6d.*—Dr. Alex. Robb, Edinburgh.

*£2 2s.*—Drs. H. Hanslow Brind, West Byfleet,; *Mabyn Read, and *P. H. Stirk.

*£1 1s.*—*Drs. George Adkins, *F. J. Allan, Sir Robert A. Bolam, Newcastle-on-Tyne; *Joseph Coates, Howard Davies, Pontypridd; R. Green, Stroud; H. W. Harding, Edmonton; *A. Bostock Hill, T. E. Hincks, Hay; *J. Johnstone Jervis, C. Courtenay-Lord, Orpington; Edward H. Nash, Cranford; *H. Cooper Pattin, *W. G. Savage, *C. E. Tangye, T. M. Tibbets, Old Hill, Staffs; W. W. Wells, Bromyard; ‡ James Wheatley, Shrewsbury; and J. Arthur Wood, Rugby.

*10s. 6d.*—H. Dundas McCall, Leominster.

* Per *The Medical Officer.*
† Per *British Medical Journal.*
‡ *Second subscription.*

## HOUSE OF LORDS.

### TUESDAY, JUNE 8TH.

### *Midwives and Maternity Homes Bill.*

The House went into Committee on the Midwives and Maternity Homes Bill, the EARL OF DONOUGHMORE in the chair.

Part I. of the Bill amends the Midwives Acts, 1902 and 1918. Clause 1 provides that if any person, being either a male person or a woman not certified under the Bill, attends a woman in childbirth otherwise than under the direction and personal supervision of a duly qualified medical practitioner, that person shall, unless he or she satisfies the court that the attention was given in a case of sudden or urgent necessity, be liable on summary conviction to a fine not exceeding £10.

Lord STANMORE moved an amendment to provide that the clause should not apply in the case of a person who, while undergoing training with a view to becoming a duly qualified medical practitioner or a certified midwife, attended a woman in childbirth as part of a course of practical instruction in midwifery. He explained that his object was to safeguard the midwifery training of medical students and pupil midwives. As the clause stood no medical student could attend a woman in childbirth, except under the personal supervision of a qualified medical practitioner. It was possible that, in the future, the courts might hold that the words "personal supervision" implied the actual presence of a qualified medical officer. If that were to be the case the present system of midwifery training would become unworkable. Referring to the training of the students, the noble lord said that it was very unusual where a student had to deal with an emergency case, that the delay of an hour or so before a qualified practitioner came had any bad effect on the patient. The student, having had four years obstetrical training, was in a position to give general treatment while awaiting the arrival of his colleague. He did not think any authority on obstetrics would consider it necessary that a student should be accompanied by a medical man in all the cases that he had to attend. On the contrary, he could not learn his work properly without having responsibility during his period of training. The case of the pupil midwife was very similar to that of the student. An untrained woman had to go through a course of training for 12 months and a trained nurse for six months. Training was carried out under the superintendence of experienced midwives, who were recognised by the Central Midwives Board. It was not only undesirable that they should be subjected to the personal supervision of the medical man in all these cases, but if that supervision was insisted on it might have the effect of greatly reducing the number of midwives.

Viscount KNUTSFORD, in supporting the amendment, said that only the other day all the medical schools in London met and proposed that an amendment should be moved to the Bill very similar to that of Lord Stanmore. He was sure their lordships would accept the amendment with perfect certainty that the women who were being treated would be properly attended to and that the pupils or students would be properly taught. He thought the word "training" in the amendment should be strengthened by the substitution of the words "training recognised by the General Medical Council or the Central Midwives Board." Anything might be "training," and they must be quite sure that nobody was allowed to attend a woman in confinement unless he was going through a properly recognised training.

The Marquess of SALISBURY said it was quite true that since this Bill was read a second time very strong representations had been made to the Ministry of Health and the Government in regard to this particular point. It had been represented to them that if the clause passed in its present form it would lead to considerable difficulty in the training both of medical students and pupil midwives, and would really constitute a great disadvantage to the public interest. On the other hand, of course, they had to safeguard the women concerned and they could not agree to any amendment which did not in its terms adequately protect the women. The amendment proposed by Lord Stanmore was designed to steer a middle course between two extremes, and he thought that on the whole he had succeeded. As regarded the words suggested by Lord Knutsford it ought to be considered between now and the report stage whether they were necessary. He thought Lord Stanmore's amendment was required. They did not want to interfere with the great schools of medical training; that was a matter of national importance. It was a tremendous charity which these women were receiving, because they were attended by the medical students and pupil midwives for nothing. He understood that no medical student would be allowed to act in these cases except towards the end of his training. In other words, the medical student was almost a qualified doctor before he was allowed to attend midwifery cases. The pupil midwife was not allowed to attend them except in the presence of a trained midwife, who showed her how to do her work. Therefore he thought their lordships might be assured that adequate care was taken.

Lord DAWSON said that the remarks of Lord Salisbury as to whether the public were adequately protected in the course of medical education were of considerable public interest. It was very important that the public should be reassured on that point. The public were adequately *protected for this reason. To begin with, the medical student* when he started his training had been through several years of preliminary education. He had been trained in the basic sciences on which medicine was built. That was one advantage he had over the midwife. Before he was sent out to practise midwifery he was put through a course of education in the hospital where he was given actual instruction in maternity cases. Having got so far it was very important to send the student out so that he could learn to be self-reliant. One of the most delicate questions in regard to medical education was as to the right moment when the medical student should be sent out to cases on his own, with the right sort of advice in the background. But when he did go out he went with the full knowledge that if the case to which he went was abnormal or any difficulty presented itself he could immediately send for a highly skilled person. It was far better that a medical student should be trained in the habit of self-reliance during his period of education than that he should postpone it until he went into practice and had no one behind him. In actual practice the system worked extremely well. The service was very popular. The patients themselves were attached to the students, largely because they found themselves coming into contact with the innate friendliness which seemed to be part of the make-up of the British medical student. The students, on the other hand, found how closely allied were the human and scientific sides of their art. Altogether it was an excellent arrangement, not only in regard to the training in medicine, but also to the training in the management of people. The patients got very fond of the students and the latter generally ended their week on duty with larger hearts, but certainly with emptier pockets. He had been through this training himself. Before now he had washed a baby and baptized a baby; how efficiently he did not know, but he rather thought he found the baptism more easy than the washing. He thought that the machinery of medical education and the public interest would both be damaged if some sort of amendment as that proposed by Lord Stanmore was not inserted in the Bill.

The amendment was agreed to, and Clause 1 as amended was added to the Bill.

Lord STRACHIE moved to leave out Subsection (1) of Clause 2, which provides that where a midwife has been suspended from practice in order to prevent the spread of infection she shall, if she was not herself in default, be entitled to recover from the local supervising authority such amount by way of compensation for loss of practice as is reasonable in the circumstances of the case. He said that he moved the amendment at the request of the County Councils' Association. So far as they were aware there had never been any injustice done in regard to this matter. Sir Kingsley Wood, the Parliamentary Secretary to the Ministry of Health, had defended this clause, because he said that one or two authorities in the past had not acted fairly to the midwives who were suspended. He (Lord Strachie) thought that it would have been more reasonable if Sir K. Wood had taken the trouble to inform the Committee who these local authorities were and of the circumstances of the particular cases to which he referred. If there were only one or two cases he did not think this clause was necessary.

The MARQUESS OF SALISBURY said it was vital to remember that if there was the least temptation on the part of those concerned to conceal possible contact with infection, grave risks would arise. Although he was a very great advocate of local government independence the Government were more concerned with the safety of the patients and were very anxious to go the whole length they could in order to protect them. Lord Strachie had truly said that the great body of county councils would act with due regard to the interests of their patients and in a proper public spirit in matters of this kind. The Government wished to reassure the midwives themselves; to make them certain that they would get compensation, in ensuring that they would run no risk of carrying infection into the homes of the patients and thereby risking their lives. For that reason he hoped the amendment would not be pressed.

Lord STRACHIE withdrew the amendment.

In Part III. of the Bill, Clause 11 interprets the expressions used. It is defined that the expression "Maternity home" shall not include "any hospital or other premise for the conduct of which a duly qualified medical practitioner resident therein is responsible."

The ARCHBISHOP OF CANTERBURY moved an amendment providing that there should be lodged with the local supervising authority a *certificate signed by two duly qualified* medical practitioners, practising or residing in the county, not being in partnership with the first-mentioned practitioner, or each other, and having no financial or other interest in the hospital, to the effect that the premises and their equipment were in all respects suitable for the purpose, and that the medical practitioner carrying on or proposing to carry on such a hospital was a fit and proper person to carry *it on. He said that the clause, as it stood, practically said* that any man who had attained due qualification in medical work was to be exempted from inspection if he opened a home for the purposes referred to in the Bill. He yielded to no one in his whole-hearted admiration for the medical profession. No profession in the world stood higher in regard to the character of its members and in regard to their public spirit and desire in all cases—and their qualification *in almost all cases*—to act in the public interest and to do what was right. But even in that great profession there might here and there be a man who, while possessing the technical qualifications, could not be regarded as altogether relieved from the possible suspicion of having other motives in what he might be endeavouring to do. In order to protect the homes, the medical men, and the public there ought to be some qualification of the complete exemption which was offered to a man who might be opening a home, dealing with this delicate and difficult matter, entirely on his own responsibility. He had taken the wording of the proposed safeguard from the General Purposes Act of the London County Council (which body had the same matter to deal with), which laid down the restrictions in its case.

Lord BANBURY supported the amendment. It was absolutely necessary that there should be some safeguard to prevent a person starting a home of this sort merely in order to make money out of it. Such a person perhaps might be not properly qualified, or might not have been a success as a medical practitioner. He was not quite certain that all nursing homes were what they should be.

The MARQUESS OF SALISBURY said that there was no difference of opinion between the Government and the Archbishop of Canterbury as to the absolute necessity *of some such* limitation of the clause. Undoubtedly what Lord Banbury had said was true—that there were a certain number of maternity homes which were anything but admirable places; in fact, very disreputable. The only real question was what form the amendment should take. There was a good deal to be said for the Archbishop's proposal, but the method of trying to effect a safeguard by a definition and by a certificate of other medical practitioners was not a wholly *satisfactory* way of meeting the difficulty. The suggestion, of course, was that there were a certain number of black sheep in the medical profession who might misconduct a maternity home. The number might be very small out of all the medical men in the country, but it would certainly not be impossible for one black sheep to find two other black sheep. That was really the only protection which the Archbishop's proposal gave. No doubt they must not be technically in partnership with the medical practitioner himself; but there were all sorts of indirect methods by which evasion could be carried out. The Government therefore thought the object in view would be better achieved by a safeguard of a totally different kind. Instead of trying to fortify one medical practitioner by two others, they suggested that it should be made a matter of discretion by the supervising authority. They proposed that the supervising authority should have absolute discretion to say that they would not certify a particular home, and in that way, through having local knowledge, they would be able to protect the public and the women concerned. That was to say, only those would be exempted from the provisions of Part II. of the Bill who got an exemption from the local supervising authority, leaving it open to the authority to refuse an exemption when they thought fit. That would be the only really efficient safeguard. It might be said that to leave the discretion wholly in the hands of the supervising authority was going too far. The Government agreed with that view, and they were providing an appeal in order to prevent any possible injustice following upon this amendment.

Viscount HALDANE said that on the whole he preferred the Government amendment, and he thought the House should adopt it.

Lord MERRIVALE said that the proposal of Lord Salisbury was much more stringent than that of the Archbishop of Canterbury. He supposed that the local supervising authority would not see fit to exempt anyone from the operation of the general law unless they were satisfied that they ought to be so exempted.

The ARCHBISHOP OF CANTERBURY said that after what had been said he would withdraw his amendment provided that he might bring it up again on the report stage if he found it to be necessary.

The Archbishop of Canterbury's amendment was by leave withdrawn.

Amendments to Clause 11 were moved by Lord SALISBURY providing (1) that any hospital or other premises, for the conduct of which a duly qualified medical practitioner resident therein was responsible, might be exempted from the provisions of Part II. of the Act by the local supervising authority; and (2) that any person who was aggrieved by the refusal of such authority to grant exemption, or by the withdrawal of exemption might appeal to the Minister of Health, who might give such directions to the local authority as he thought proper.

Viscount KNUTSFORD said that if the Bill passed in its present form any hospital or other premises maintained or controlled by a Government department or local authority or by any other body of persons constituted by special Act of Parliament, or incorporated by Royal Charter would be exempted from registration. Hospitals under a Government department or a local authority needed inspection rather more than others. He once saw a Poor-law infirmary in Great Britain where there were 800 patients, 200 of whom were very seriously ill indeed. There was a resident medical officer who was responsible for the management, and therefore that hospital would be exempted from this Act. There was a filthy syphilis ward, and only one medical officer who had to do all the post-mortems and attend the delivery of women. She was a girl 26 years of age, holding her first appointment. When he exposed this case he was called a liar. The City Fathers denied that such a thing ever existed, but he was glad to say that they had to admit it in the end and the conditions were altered. That was an instance where inspection by the supervising authority would have done infinite good. So far as the voluntary hospitals were concerned the more they were inspected the more those who were responsible for them would be pleased. He hoped the Government would agree to take out the provision exempting these institutions from registration and inspection.

The Marquess of SALISBURY said that Lord Knutsford would like to see all hospitals brought within the restrictive provisions of the Bill. That was a view which, coming from him, one was bound to treat with very great respect, but his (Lord Salisbury's) impression was that the great body of hospitals did not quite share the noble lord's opinion. What the Government had to consider was how far they could carry exemption safely, and the clause together with the amendments had been drawn so as to cover the ground as well as possible.

Lord Salisbury's amendments were agreed to and Clause 11 was added to the Bill.

The Bill passed through Committee and was reported to the House.

## HOUSE OF COMMONS.

### THURSDAY, JUNE 3RD.

### *Progress in Housing Construction.*

Mr. TREVELYAN THOMSON asked the Minister of Health the number of houses at present sanctioned for construction under the various Housing Acts, and similar figures for a year ago.—Mr. NEVILLE CHAMBERLAIN replied: Up to the end of May, 1926, 292,067 houses had been authorised for erection under the Housing Act of 1923 and 126,138 under the Act of 1924. The corresponding figures for May, 1925, were 205,030 and 58,350 respectively.

### *Economy in Poor-law Relief.*

Mr. CONNOLLY asked the Minister of Health why he had intimated to the Newcastle board of guardians that any further loans required by them and sanctioned by him would be contingent on their acceptance of the suggestions contained in Ministry of Health Circular 703, which placed the maximum amount of relief at 35s. per week; whether he was aware that this circular stated that the instructions concerned the general stoppage of industry, which no longer existed; and whether he proposed to give the House an opportunity of discussing the effects of such provisions on the health of the Poor-law relief recipients, and particularly the children.—Mr. NEVILLE CHAMBERLAIN replied: It has already been necessary to sanction the raising by this board of guardians of temporary loans to the amount of £200,000, and, in view of their financial position, it is essential that every practicable economy should be adopted. The reduced scales of relief now in force are still higher than has been found necessary in a number of other unions. The basis of Circular 703, which is incorrectly described by the hon. Member, was that guardians should make adequate arrangements for carrying out their statutory duty of relieving destitution while taking all possible steps to conserve their financial resources in view of the demands that might be made upon them. The principles of the circular will continue to be applicable during the coal dispute which must result in increasing demands upon the guardians. The question of discussion in this House is one for arrangement through the usual channels.

### *Report of the Lunacy Commission.*

Sir CHARLES OMAN asked the Minister of Health when the Report of the Royal Commission on Lunacy could be laid before the House.—Sir W. JOYNSON-HICKS (Home Secretary) replied: I am unable to state the date on which this report will be laid before the House, but I understand that the Royal Commission hope to be in a position to present their report before the end of next month.

### FRIDAY, JUNE 4TH.

### *Lead Paint Poisoning.*

On the order for the second reading of the Lead Paint (Protection against Poisoning) Bill,

Sir W. JOYNSON-HICKS (Home Secretary) said that two proposals were made at Geneva for dealing with the evil of lead paint poisoning. One was that the use of lead paint should be prohibited altogether, and the other that every effort should be made by regulation to minimise the danger arising from its use. There was a very great demand for the use of lead paint, and the employers who used it told him quite clearly that the substitutes that had been suggested were not satisfactory. He was not prepared at present to go the whole length of prohibition, because it had not been proved to his satisfaction that it was necessary. But he was prepared to give the Labour Party the half-loaf of regulation, and the choice that day lay not between half a loaf or a whole loaf, but between half a loaf and no bread at all. The regulations contemplated by this Bill had been agreed to by employers and employees, and they would enable substitutes to be used in order to reduce—he would not put it higher than that—the possibility of poisoning by lead paint. He was not going to say that this was final; it was an experimental measure. He was as determined as anyone on the Opposition side of the House to do all he could to reduce the evils of lead poisoning, and if he found that the regulations were not sufficient, and that lead poisoning still went on, he would not hesitate to come to the House again for a Bill which would prohibit the use of lead paint. He had great hopes that the effect of the regulations would be, if not to stamp out the evil completely, very largely to reduce it, and to make the conditions of the workers better, happier, and far less dangerous than they had been in the past.

Mr. R. J. DAVIES, speaking on behalf of the Labour Party, pointed out that the Bill did not ratify the Convention passed at Geneva, and contended that it was grossly unfair for the Home Secretary to ask the House to pass a Bill which in no way met the demands of that Convention. No votes had been cast against the Convention at Geneva, and there had been only one abstention. In 1924 the Labour Government produced a Bill embodying the Convention. The master painters and the operatives were at one in favour of ratification, which was more important in view of the increased number of men suffering from lead paint poisoning. In 1919 the total number of sufferers in this country was 207; in 1922 the number was 246; in 1923 it was 337; and in 1924 it had increased to 486. If this Bill was carried the Home Office would be unable to enforce the regulations. There were about 70,000 house painters and decorators in the country, and they were employed in twos and threes in different houses. How was it possible in these circumstances to enforce the proposed regulations?

Sir W. JOYNSON-HICKS said it was proposed to increase the number of inspectors, and it was his experience that trade-unions quickly warned their members of the existence of new regulations, and that the men soon reported breaches to their unions.

Mr. DAVIES said that the Home Secretary was too sanguine. If the Office of Works, the chief painting department of the State, dispensed with white lead in paints he saw no reason why its use should not be prohibited throughout the country.

Lord H. CAVENDISH-BENTINCK, a Unionist Member, said that the regulations that were proposed would not only be useless, but would prejudice the onward progress of reform. How long were they to wait, and how many people were to have their health ruined while the Home Secretary was waiting? He was more annoyed than he could say that a Conservative Government should have brought in such a rotten and useless measure.

Mr. VIANT, in moving the rejection of the Bill, said he was speaking from experience as a man associated with the trade. When a painter caught the disease it was often transferred by him to his wife and children. Adequate substitutes existed for lead paint, and its use in interior work was quite unnecessary. One of the regulations provided that before a painter got employment he must show a clean bill of health. That would impose upon the painter and his family the taint of pauperism unless it was accomplished by the payment of financial assistance while the painter was unemployed. Factory inspection to-day was a farce, and if the regulations proposed were practicable they would also be a farce.

After further discussion,

Captain HACKING (Under-Secretary to the Home Office) said it must be remembered that since the Geneva Convention the position had been very largely modified, and procedure by regulation had become more practicable because of the inventions that had taken place, and one of the most important was the invention of waterproof sandpaper.

The second reading of the Bill was carried by 131 votes to 56—majority 75.

### MONDAY, JUNE 7TH.

### *The Taxation of Medicines.*

The House went into Committee on the Finance Bill, Mr. J. HOPE, Chairman of Committees, in the chair.

Clause 2 provides that the additional duties of excise imposed by Section 11 of the Finance (No. 2) Act, 1915, upon medicines liable to duty shall continue to be charged, levied, and paid until August 1st, 1927.

Captain WEDGWOOD BENN asked the Financial Secretary of the Treasury to look into this clause which, he said, dealt with matters going back to the seventeenth century. It would be much simpler from the point of view of the taxpayer if the Treasury would produce a clause showing what would be levied instead of referring in the clause to another Act, and then by that to another Act, and so on back to nearly the year 1600.

Mr. R. MCNEILL (Financial Secretary to the Treasury) said that when Captain Wedgwood Benn raised this matter last year his predecessor gave an undertaking that the matter would be considered before the introduction of the present Finance Bill with a view to a codification of the various old statutes. After consideration it had been decided that codification by itself would be useless. What was needed was a drastic revision of the statutes. That, however, had not been possible before the introduction of the present Finance Bill, but it was intended in the near future to appoint an interdepartmental committee to consider exactly what ought to be done in order to get rid of the superfluity of old and obsolete statutes dealing with particular specifics. There was one particular specific in the schedule called the Elixir of Longevity. He did not think that elixir had succeeded in achieving longevity although it had remained in the schedule to the Statute of 1812. He understood that the elixir was no longer efficacious and that showed that mere codification would not meet the case. He hoped that before this time next year they would have done something to remedy the present state of things in this respect.

The clause was agreed to.

### *Health Conditions on Emigrant Ships.*

Colonel DAY asked the Secretary of State for Dominion Affairs if he was aware that the Shaw, Savill, and Albion Company's steamer *Tainui*, which sailed for New Zealand on Jan. 8th, 1926, with 428 third-class passengers, was not adapted or suitable for use as an emigrant ship; that the temporary four- and six-berth cabins were not adequately ventilated; that the bathing and washing arrangements for both men and women were inadequate; and that no water was available in the cabins four days after leaving England; and, in view of these discomforts and the danger to health experienced by these emigrants, would he, in conjunction with the New Zealand authorities, cause full inquiry to be held in this regard.—Sir BURTON CHADWICK (Parliamentary Secretary to the Board of Trade) replied: The *Tainui* was built under Passenger Certificate Survey in 1908, and has since, with the exception of the war period, been engaged in carrying emigrants to New Zealand. Before leaving this country on her last outward voyage, she was surveyed by Board of Trade surveyors, when the ventilation, bathing, and washing arrangements were found to be in excess of the requirements of the regulations. The ship has been again inspected by the Board's surveyors, and they report that the officers and stewards of the ship state that they received no complaint of lack of water in the cabins. The stewards state that the supply tanks were filled regularly each morning from a fresh-water tap fitted in each section of the passenger accommodation.

### *Government Nominee on the G.M.C.*

Mr. FORREST asked the Vice-Chamberlain of the Household, as representing the Lord President of the Council, whether the Crown nominee on the General Medical Council would make any annual report to the Government on its proceedings; and whether, in that case, the document would be published.—Major HENNESSY replied: The hon. Member appears to be under some misapprehension. The meetings of the General Medical Council are open to the public and are reported in the daily press and professional journals. The official minutes of the proceedings are published and are supplied to the Privy Council, and are also available to the public.

Mr. HORE-BELISHA asked whether Mr. Hilton Young would answer questions in the House of Commons concerning the General Medical Council.—Major HENNESSY replied that he was afraid he could not answer that without notice.

### TUESDAY, JUNE 8TH.

### *Crown Nominees on the General Medical Council.*

Viscount SANDON asked the Vice-Chamberlain of the Household, as representing the Lord President of the Council, whether, seeing that the Lord President controlled a large number of nominations to the General Medical Council, he would nominate at once, or at the earliest possible moment, a number of non-professional persons, in view of the fact that the one just appointed could not possibly fill his rôle adequately if alone amongst 37 other medical members.—Major HENNESSY replied: The Crown nominees to the General Medical Council are five in number and nominations can only be made under the statute when vacancies occur.

Viscount SANDON asked the Vice-Chamberlain of the Household, as representing the Lord President of the Council, whether the Lord President's nominations to the General Medical Council were made for life, or on what basis.—Major HENNESSY replied: The nominations of His Majesty, on the advice of his Privy Council, to the General Medical Council are made for five years under the Medical Acts.

## ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the Committee 40 cases were considered and £507 voted to 31 applicants. The following are notes on some of the cases relieved:—

Widow, aged 70, of M.R.C.S. Eng. who practised in Wiltshire and died in 1896. She has worked hard for the last 30 years, and has kept and educated her three children who are now only able to maintain themselves. Applicant has been living with her sister aged 80, but on account of her great age cannot nurse the applicant who has been removed to a nursing home. Only income £98 per annum, and the Fund has been asked to help with the nursing home fees which amount to 2 guineas a week. Voted £6 in three monthly instalments of £2 each.

L.R.C.P. & S., aged 69, who practised in Scotland until ill health obliged him to sell his practice. Is now suffering from cerebral hæmorrhage and paralysis. Friends have applied to the Fund for assistance to meet expenses otherwise the doctor will have to go to the workhouse. The Hutcheson Charity is also being approached with a view to obtaining some additional assistance. Voted £40 in 12 monthly instalments.

Widow, aged 65, of M.D. Glasg. who practised in the north of Scotland and died in 1903. Two daughters, aged 24 and 22; the eldest is at home, and her only income is £30 per annum, the youngest has just passed her exams., and is now self-supporting. Since 1917 the applicant and her daughters have been fortunate in having a cottage at a nominal rent of £5 per annum, but the farm has now new tenants and the cottage is to be vacated which will involve the applicant in a heavier rent in future. Voted £10.

Widow, aged 47, of M.D. who practised in London and has been an inmate of a mental hospital since 1909. Applicant and son went out to Canada in 1923 and worked on a farm; the son also studied and passed his matriculation and was awarded a scholarship for four years, but was unable to make use of it as towards the end of that year (1924), owing to his eagerness to earn additional money; the physical and mental strain brought on heart trouble which has completely disabled him, and he is now in bed. The applicant is also in very poor health and application for assistance was made to the Fund to help them under these pitiable circumstances. Only income £150 per annum. Voted £10.

Widow, aged 49, of M.B. Edin. who practised in Wales and died in March. Two sons, aged 20 and 16; eldest a journalist earning £120 per annum, and the youngest is at present living with friends. Applicant hopes to get the youngest boy out to Australia. It is estimated that there will be very little left from the husband's estate when everything is settled. Applicant will have to take a post and become self-supporting. Voted £15 in three monthly instalments of £5 each.

M.D. 1880, aged 72, who practised in London but has had to give up practising on account of bad eyesight. His four children help as much as they can, but the brunt of the household expenses falls on the daughter, which leaves insufficient for her own personal needs. Voted £40 in four quarterly instalments of £10 each.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., at 11, Chandos-street, Cavendish-square, London, W. 1.

East End of London. In Northumberland and Durham the bulk of the working classes live in homes of two or three rooms, whereas in the rest of England and Wales a similar population lives in homes of three or four rooms.

Of course, the free colliery house, or indeed any kind of colliery house, is not the only factor in the causation of this exceptional and deplorable state of affairs. A shipbuilding town like Jarrow shows an even higher percentage of overcrowded persons. But it is the opinion of many who know the two counties well that the free colliery house did much in the past to set the standard of housing; and when the shipbuilding towns grew up, they grew up in areas where one or two rooms were considered good enough for a working-class family. If the set purpose had been to check ambition for better homes, no better way could have been devised to achieve that end than the free colliery house system. A family, which might have struggled and sacrificed in other circumstances to obtain something better, would obviously not do so whilst a home of a kind could be had for nothing, and was indeed part of the wage. The colliery owners on their side had little incentive to build well, and some real difficulties; much coal-mining has been of a speculative nature and leases were often for 21 years only, so that there was a considerable risk of losing capital sunk in building schemes. The more credit is due to those exceptional colliery companies which have built model villages against which no serious criticism can be levelled.

Whilst the homes of Northumberland and Durham are exceptionally small the families are exceptionally large. The birth-rate in Durham, whilst falling as elsewhere, is roughly 50 per cent. above the birth-rate for England and Wales as a whole. On the north side of the Tyne the birth-rate is not quite so high, but it is well above the average for the country. Marriages are early; in Durham, a few years ago, one bride in four was under age. With regard to overcrowding and a high birth-rate, there is almost certainly a circle of cause and effect; young men and young women are glad to escape as soon as possible to make a fresh home, and there are other obvious ways in which overcrowding operates. In Northumberland and Durham there is the further unfortunate feature that over most of the area the sanitary arrangements are bad. Even Gateshead, with its 130,000 inhabitants, is only now converting to water-carriage, and in most of the Tyneside towns, as well as in the Hinterland, a considerable number of ash privies or of pails will be found. Naturally there is a high infantile mortality. The actual figures are rather better than might have been supposed, perhaps because of the energy of the public health officials, but the infantile mortality rate for the county of Durham has been for the last 20 years between 12 and 20 per 1000 above that of the country as a whole.

If it should happen, as seems very likely for economic reasons, that there should take place a closing of pits on a large scale and a migration of miners to other areas, there will be a great deal of suffering in the process and anything possible should be done to mitigate it. But it would not be without compensation. It would mean the thinning out of the most overcrowded homes in England and Wales, and there would be for thousands of families a compulsory break with a bad tradition. The newer coalfields are not cursed with the free colliery house and with the deplorably low standards with which the north-east corner of England is infected.

### THE SOUTH WALES COALFIELD.

The South Wales coalfield is not so old as some of the others (e.g., South Staffordshire and Northumberland), and the housing conditions are proportionately more modern. The coalfield is broken up into a series of narrow valleys, on the sides of which the miners' dwellings are built in ascending rows. During the winter months the hills keep any sun there is from gaining access to the valleys, while the steepness of the banks upon which the houses are built militates against the provision of recreation facilities. Nevertheless, in recent years much is being done through the grants provided by the Miners' Welfare Fund to improve this latter position.

When the health of this community is examined, it is found to have been in recent years more favourable than might have been anticipated. The mining community form with their dependents at least three-quarters of the total population of the county of Glamorgan. The birth-rate of the county, which was 31·0 in 1914, declined to 23·1 in 1919, and after a rise in the post-war years fell again to 21·8 in 1925; these rates have been throughout higher than those for England and Wales, for which the birth-rate was 23·8 in 1914 and 18·3 in 1925. The general death-rate has consistently, since 1912, been lower than that for England and Wales; it was 13·5 in 1914, 11·7 in 1919, and 11·2 in 1925; the corresponding rates for England and Wales were 14·0, 13·8, and 12·2. Infant mortality is usually considered a delicate index to the health of a community, and is of particular interest for a community like the coal-miners, who have always exhibited a high birth-rate. In 1904 the mortality for the county was 170 as compared with 140 for the Kingdom. In 1918 it had fallen to 95, when it was actually below that, 97, for the Kingdom; in 1925 it was 83 as compared with 75. Taken as a whole these mortality records must be considered as favourable for a coal-mining population. A further point throws some light upon the sanitary state of the buildings, of which the prevalence of enteric fever is held to be some indication; in 1901 the death-rate from this disease was 0·39 for Glamorgan as compared with 0·23 for the Kingdom—it had fallen by 1925 to 0·01 as compared with 0·006.

At the present moment relief coming from either public resources, such as the feeding of school-children, unemployment benefit, or from such sources as strike pay and private contributions, place any industrial community, temporarily thrown upon its own resources owing to cessation of work, in a better position than it would have been 20 years ago. The systematic feeding of school-children was instituted in the county, the Whitsuntide holiday being suspended so as to permit provision of meals to continue without a break. The mining community is suffering undoubted privations, a position which reacts promptly on the small purveyors.

## LEBANON HOSPITAL FOR MENTAL DISEASES.

THIS hospital is the only one of its kind in the Near East. For the last 17 years Dr. H. Watson-Smith has been director and throughout the war he was able to carry on the work steadily, though virtually a prisoner in the hands of the Turks. Since then the buildings have been repaired and the work developed. During the past year 135 patients (83 men and 52 women) were admitted. From the previous year there remained 95 patients (48 men and 47 women), making a total of 230 patients (131 men and 99 women) under care and treatment throughout the year. Of this number 33 (16 men and 17 women) were discharged completely recovered and enjoying full mental health. Thirty-seven patients (25 men and 12 women) were discharged improved, although the nature of their malady renders it possible that they may relapse in the future. Fifteen men and 3 women were discharged as not improved, several of these being removed by impatient relatives against medical advice Primitive methods of treatment in the form of exorcism are still much in use.

At the twenty-seventh annual meeting of the hospital held at the rooms of the Medical Society of London on June 1st, the chairman of the General Committee, Dr. E. W. G. Masterman, presided. He had recently visited the hospital, and he said that boring to a depth of another 300 feet, where an ample constant supply of water would be available, was vital to the well-being of the community. The number of acute women patients was increasing, and single room accommodation for these was becoming pressing. Such cases were unlikely to decrease during the present troublous times in Syria. The payments of the French Government for necessitous cases had fallen in value with the fall of the franc. Dr. Masterman paid a tribute to the valuable work of the executive committee in Beyrout.

Mr. W. A. Albright, J.P., one of the trustees, who had also lately visited the hospital, said that far more facilities for curative open-air occupation would be opened out when the land could be irrigated and brought under cultivation. Mr. F. Hourani spoke of the great service of the hospital to the Syrian nation and hoped that in course of time Syrians would take the burden of the work upon their own shoulders. Dr. J. F. Whitwell presented the report of the medical director, which includes statistical tables showing the prevalent forms of mental disorder in the East. Dr. Fortescue Fox referred to Asfuriyeh as a centre of treatment, of teaching, and of research. The resident fifth-year students to be supported by the Rockefeller Foundation would be of assistance to the Director in his work as clinical professor of psychiatry in the American University of Beyrout. Dr. Fox looked forward with confidence to further light being shed from this centre upon the difficult problems associated with mental disease. Mr. Joseph Butler, senior honorary treasurer, stated that over £4000 a year was contributed in Syria itself on behalf of patients. Dr. Percy Smith mentioned that it was at Bethlem Hospital that the general committee first met. Dr. Bedford Pierce moved a vote of thanks to auxiliary committees in America, Switzerland, and Holland.

Copies of the report can be obtained from the general secretary, Miss Hilda Fox, 67, High-street, Marylebone, W.1.

---

DONATIONS AND BEQUESTS.—Under the will of the late Mr. Milton Haydock, of Churchfield House, Great Harwood, Lancs, the testator left £2000 to the Blackburn and East Lancs Royal Infirmary.

# A Lecture
ON
# FREUDIAN PSYCHOLOGY.

*Delivered at the Institute of Pathology and Research, St. Mary's Hospital, on June 3rd, 1926,*

BY CHARLES S. MYERS, M.D.,
SC.D. CAMB., F.R.S.,
DIRECTOR, NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY.

WHEN I was asked to give an address on the scientific value of Sigmund Freud's contributions to psychology I recognised at once the impossibility of dealing adequately with the subject—in the first place within the compass of an hour's lecture, and secondly without having familiarised myself with the numerous accretions and modifications to which in recent years Freud has been subjecting his earlier views. The latter of these difficulties I have endeavoured to remove, so far as I could. The former will inevitably prevent me from entering into many, I hope less important, details of the subject.

### THE "ALL-OR-NONE" ATTITUDE TOWARDS FREUD.

I accepted the invitation from selfish and unselfish motives. On the one hand, I had long wanted to form for myself a more exact judgment of the value of Freud's teachings. On the other hand, I recognised that few had ever made this attempt in any spirit of impartiality or after adequate training in normal psychology. The reaction of nearly all of Freud's followers and opponents has been an emotional one—an "all-or-none" response. Either nothing could be right or nothing could be wrong, within the vast psychological structure which Freud has erected. Such an attitude is the natural result of the play of lower uncritical levels. Few physicians have had the psychological training to view Freud critically. Medical education is still apparently based on the supposition that only material processes in the living organism are worth studying and that normal psychology and psycho-physical methods have nothing to teach, as if mind did not exist and were of no therapeutic value for general medicine.

### FREUD'S OWN CONFLICTS.

Freud himself is not a trained psychologist. Had he been, it is quite possible that his developing genius would have been so stunted by the (now superseded) psychological doctrines of his day, that his brilliant contributions to the subject—of such varying worth—would have been altogether denied to us. Contempt is often nature's cloak for ignorance, but it is not altogether unjustifiable, because of the errors of its youth, that Freud despises or ignores current psychology. Of him the psychologist might say what Dostoievsky, so I have read, once said of himself: "I am called a psychologist. It is wrong. I am simply a realist in the higher sense of the word; that is, I depict all the dim recesses of the human soul." Unfortunately, the untrained psychologist is only too easy a prey to the *prime psychological fallacy*—that what he finds in his own mind he assumes to exist in the minds of all others. I suspect that Freud is too often unwittingly depicting 'the dim recesses of his own soul," within which affection so clearly conflicts with enmity, generosity with despotism, inferiority with ambition, and the volatile, volcanic temperament of the artist with the conscientiousness of the man of science.

For Freud has himself stated that throughout his life he has always found the emotional need both for "an intimate friend and a hated enemy,"[1] whether in different persons or in the same person at different times. A few years ago I sent a young pupil to see Freud, who reported to me that when he remarked to Freud that he had just met one of the most distinguished men—let us call him X—who had seceded from the Freudian school, Freud declared himself totally ignorant of X, insisting "Ich kenne ihn nicht." Freud's father, it is on record, told a friend that his little Sigmund would never dare to contradict him. As a boy, and no doubt later, he was subject to all the indignities and contempt inseparable from an anti-semitic atmosphere. In my experience a lack of mental balance is notable, too, among Freud's followers, both among his lieutenants and in the rank and file. At least three suicides are on record within the narrow range of Freud's own psycho-analytic circle in Vienna.[2]

### HIS PSYCHO-ANALYTIC SCHOOL.

We have to remember that no one can be considered a true psycho-analyst unless he has himself submitted to psycho-analysis, that such psycho-analysis must be conducted by Freud or by one of his more or less immediate lieutenants, and that the process of psycho-analysis necessarily involves what is technically known as "transference," in which certain peculiar relations between the analyst and his subject develop, that invite uncritical acceptance of his views. To these relations I shall return presently.

Freud has thus founded a "school" of which he is the despotic, infallible, quasi-papal head; and to be an apostle of it thus involves the laying-on of hands. As leader of the school he has been compared to the leader of a herd who drives out any members who attempt to usurp his authority. This attitude his enemies ascribe to ambition and intolerance, his devotees to the necessity of protecting his teachings from all risk of charlatanry and pollution. It is not surprising, and certainly not altogether blameworthy, if in framing the many later additions to and modifications of his original views, Freud has at times adopted attitudes closely similar to those which he originally condemned in those of his pupils who were forced to part company with him. These accretions have been of late so numerous and sometimes so much at variance with his previous views that it becomes difficult to criticise some of them in close detail. Six years ago Freud wrote: "I might be asked whether I am myself convinced of the views here set forward, and if so how far. My answer would be that I am neither convinced myself, nor am I seeking to arouse conviction in others. More accurately, I do not know how far I believe in them."[3]

### PSYCHO-ANALYSIS AND HYPNOSIS.

But the airy way in which Freud treats such hypotheses as mere embellishments of decorative value cannot apply to the theory and practice of psycho-analysis. This forms the foundation-stone for all his later superstructure. It arose, as is well known, from Breuer's discovery that cures were possible in psychoneurotics by bringing back to consciousness their repressed memories through the influence of persuasion under hypnosis. Breuer believed that an essential factor in such cures was the release of a hitherto repressed emotional experience—the "ab-reaction" which accompanied the recovery of these forgotten inhibited memories. This process of psychotherapy was hence called "catharsis." It was employed in the British Army with surprising success on a large number of cases of so-called "shell shock" during the Great War.

But in Freud's hands hypnotic suggestion did not prove uniformly successful. His experience was that hypnosis "conceals the resistance" which the psychotherapist desires to reveal. He contends that "hypnosis does not do away with the resistance but only avoids it, and therefore yields only incomplete information and transitory therapeutic success."[4] That is not, however, the experience of others who used hypnosis as a rapid method of psychological analysis during the recent war. The hypnotised patient manifested points of resistance where the recovery of lost memories, recent and bygone, proved exceptionally difficult, in much the same way as the non-hypnotised patient; and there was no reason to suppose that the cures brought about by such methods of recovery of repressed experiences were transitory.

[3] *Beyond the Pleasure Principle.* English trans. 1922. London: International Psycho-analytical Press. P. 76.

In Freud's hands the procedure of psycho-analysis has undergone certain developments since its origin, but it is unnecessary to describe these here. Its broad principles have remained unchanged. The hypnotic state and the principle of catharsis are replaced by free association and interpretation. The character of the subject's associations and the interpretations of the analyst are employed to recognise resistances and repressions.

Freud's aim in psycho-analysis was much the same as Breuer's—"making conscious the unconscious, removing the repressions, filling in the gaps in memory."[5] That this aim rather than the "catharsis"—the "abreaction," or release of a suppressed emotion—is generally the correct one there can, I think, be little doubt. What is in dispute is Freud's insistence that psycho-analysis must be carried back to the patient's early memories of from 2 to 5 years of age. This, Freud maintains, is essential for true psycho-analysis. It is essential because of Freud's peculiar views concerning sexual development and the relation of sexual activity to the psychoneuroses. But we must recognise at the outset that other psychotherapists claim equal success in their treatment without extending their analysis so far backwards, and that they are wholly unable to accept Freud's views as to the *invariable* responsibility of infantile sexual conflicts and sexual maldevelopments for the psychoneuroses.

It is noteworthy that Freud's escape from the use of hypnosis may not be so complete as at first sight it appears to be. During Freudian psycho-analysis the patient lies on a couch and is asked "to put himself into a condition of calm self-observation, without trying to think of anything," and then to narrate whatever comes into his mind. But such a state of reverie, bereft so far as possible of self-control, is apt to pass into a condition not far removed from that of slight hypnosis. I have known patients at the close of a period of analysis "pulling themselves together" with a start, just as if they were passing from dreamland to the reality of every-day life. In one case I have actually seen the old personality, as it were, suddenly reappear with total oblivion once more of the suppressed memories which I had been reviving during the analysis.

### *Transference.*

As has already been mentioned, psycho-analysis does not merely consist in voluntary passive confession. The analyst is ever on the alert to recognise resistances, to interpret and to remove them, and to explain to the patient what his repressions and their distortions mean. In one description of the process of psycho-analysis I remember reading how, while the patient—of the gentler sex—is lying in a darkened room, the analyst's hand is smoothing her troubled brow, as long-repressed memories are revived and interpreted.[6] I do not wish it to be supposed that such are the usual conditions under which psycho-analysis is conducted, but psycho-analysis in the Freudian sense does involve—and it is, according to Freud, essential for success that it should involve—a very special and intimate relation between the analyst and his patient, to which he gives the name of "transference." Freud gives the following examples of this relation as described to him by the patient's friends: "He has quite lost his head over you; he puts implicit trust in you; everything you say is like a revelation to him. . . . It is positively boring the way he never speaks of anything but you; he quotes you all the time."[7] This transference, like all suggestibility according to Freud, depends on sexual attachment. In the psychoneuroses it means (in Freudian language) the gathering together of the whole of the sexual energy which has hitherto been withdrawn from the control of the ego and become attached to the symptoms, and the transfer of that energy to the analyst. Without such transference, says Freud, "the physician and his arguments would never even be listened to."[8] It "exists in the patient from the beginning of the treatment and is for a time the strongest impetus in the work"[9] of psycho-analysis. Sometimes the transference is a negative one, a feeling of hostility towards the analyst; but it is clear that such a relation cannot make for a successful issue. Women patients, we are told by Freud, fall in love with the analyst; men patients (by homosexual sublimation, he supposes) admire him. Having won this transference the analyst's great care, we are told, is to re-direct it, so as not to endanger it.

We may well wonder how far psycho-analysis, as practised by Freud, owes its success to the resuscitation of repressed complexes, how far to the peculiar interpretation, almost invariably in terms of sexuality, which he gives his patients, and how far to the extraordinarily suggestive influence which the analyst comes to exert over his patient because of this "transference." Everyone who has practised suggestion as a method of psychotherapy will have met cases of cure where, it later turned out, the patient did not really even understand the explanations given him, but accepted them by force of suggestion, not of comprehension or reason. I recall a case in which a person under light hypnosis carried out various acts to the amusement of a roomful of undergraduates. On being fully awakened, he declared that he was throughout quite aware of the absurd things he had been doing, but did them "to oblige" the hypnotist. Realising the enormous power of suggestion and Freud's stress on transference, can we from the therapeutic success of Freud's psycho-analysis justifiably infer the truth of his interpretations and of his view of the rôle of sexuality in the psychoneuroses? Can we be sure that Freud is justified in his belief that every neurotic is homosexually inclined; that every neurotic shows in his symptoms a substitute for sexual gratification; that most dreams treat of sexual material and give expression to erotic wishes?[10]

### FREUD'S TENDENCIES TO RASH GENERALISATION.

Freud's cardinal error is undue readiness for generalisation. No one will deny the sexual causation of many dreams and neuroses. But he will refuse to admit this as having a general or universal application. So, too—to take another illustration—no one will deny that *some* slips of the tongue are due to the mutual interference of two different intentions. "Is this the explanation of all cases of slips of the tongue?" asks Freud. He replies: "I am very much inclined to think so, because whenever one examines an instance of it this type of solution may be found."[11] Still, it may be, he goes on to say, that a slip of the tongue can occur without the agency of this mechanism. So far, so good. But in later years he succumbs to the temptation of rash generalisation. He maintains ultimately that for the occurrence of *any* slip of the tongue the "suppression of a previous intention to say something is the indispensable condition,"[12] and that "in every case a disturbing group of ideas—a complex—can be brought to light which alters the meaning of the intended speech . . ."[13] No one who has had experience of apraxia and of the effects of perseveration and previous association, particularly in experimental work on memory, could accept such a generalisation. Of course, every slip of the tongue has its "cause"; so, too, has every error of the pen, every act of forgetting—if only it could be ascertained. But they are certainly not all ascribable to a conflict between antagonistic intentions or to disturbing complexes.

[12] Ibid., p. 52.

[13] Collected Papers, vol. iv., p. 13 ff.

So, again, none will deny that the so-called "Œdipus complex"—in the sense of a special attachment of the child to its parent of opposite sex—exists, but that it is universally present in the development of every individual and can always be appropriately termed "sexual" is sheer generalisation based on totally inadequate evidence and opposed by other competent observers. Freud regards the Œdipus complex as the *most important conflict* which the child has to face. No one except a confessed psycho-analyst is likely to admit this, until adequate evidence obtained by the unprejudiced from a large number of normal children and adults is obtainable.

### HIS VIEWS OF SEXUALITY.

The importance of the study of the abnormal can hardly be over-estimated, but there is always a risk in applying the results of such study to normal persons. When certain neurological processes are disturbed, the result—e.g., the gait in locomotor ataxy—may have no relation to any behaviour or experience in the childhood of the individual or of the race. If certain children find their way, as Freud avers in all children, from suckling to onanism, if in certain persons the kiss may suffice for sexual gratification, if among sexual perverts *other objects and aims become* sexual substitutes, even if, in certain normal people, perverse sexual tendencies may arise when normal sexual satisfaction is prevented, we are not justified in concluding, with Freud, that in every normal person sexual perversion is latent or that what rudiments of sexual life exist in the normal child must necessarily be of a perverted order. Admitting the possibility that under certain conditions vicarious organs may be concerned in sexual gratification, we have no right to conclude that the sexual instinct has a manifold source. If sexual feeling may at times irradiate to the anal region, that does not justify us in including this region among the fundamental origins of sexual feeling.

We may allow that sexual gratification can be regarded in Freudian language as an "organ pleasure"—i.e., as a pleasure derived from the activity of a bodily organ—and we may allow that the infant derives similar organ pleasure from suckling movements in solitude—i.e., in the absence of the mother's breast or milk. But this gives us no right to speak of the infant as enjoying an "oral stage" of sexual development in which its desires are directed, narcissistically, homosexually, and auto-erotically, solely to itself.

Nor are we justified in concluding that the mouth forms part of the apparatus of the sexual instinct, because in sexual perversion it can be employed in arousing the sexual orgasm. As well might the hand be called part of the mechanism of the hunger instinct because it can be employed in satisfying hunger. The mouth may satisfy sexual appetite just as the hand may satisfy the appetite for food. But there is a world of difference between this admission and Freud's ambiguous application of the word "erotogenic" to the oral zone. We have no reason to suppose that in this region the feelings of sexual desire can normally be engendered.

We refuse, then, to follow Freud in his conclusion that because infants perform the movements of suckling "with no other object but that of obtaining pleasure," "we therefore call these areas of the body [mouth and lips] erotogenic zones and describe the pleasure derived from suckling as a *sexual* one."[14] We deny that because the child may have a preponderating affection for the parent of opposite sex, this need develop into jealousy, hatred, and a desire to kill the other parent, or that because, say, a girl child may express a desire to marry its father or its mother, this need imply anything more than a tender desire for close and permanent association with the parent. Affection is not necessarily in any sense sexual, neither in character nor in origin. It is to be found among the members of all higher organisms that live in herds; it is to be found in the tender relations of parents to offspring, not less than in those of offspring to parents. Affection belongs to the protective instinct, and develops both among those who give and among those who receive it, whether that protection relate to the herd, to the individual, or to the species. There are no grounds, then, for concluding that in childhood "an incestuous love-choice is in fact the first and the regular one." Nor can we conclude that when the child "shows at the beginning of life no disgust for excrement," he is passing from the oral to the anal stage, characterised by curiosity and cruelty, or, to use Freudian language, by sexual inspection and sadism.

A similar criticism is applicable to the so-called "castration complex." No one will deny that some young boys, when they see the female genitalia for the first time, may conclude that castration has occurred in the other sex, and that some young girls may arrive at a corresponding conclusion. But does the evidence warrant our supposing that this is a *necessary* belief occurring in all (or even in most) children, modifying an equally universal Œdipus complex, and playing an important part in the mental development of the average normal human being?

### HIS DEFINITION OF INSTINCTS.

Both hunger and sexual feeling are what the psychologist terms "appetites." But for Freud the essence of an instinct is that the stimulus should arise within the organism. Consequently he asserts that hunger and thirst are the *typical* examples of instincts, and that sexual desire is likewise an instinct because it arises from distension of the vesiculæ seminales and the like. Freud divides the instincts into sexual instincts and ego-instincts—the species-preservative and the self-preservative instincts. I will not stop to consider how difficult it is, under this classification and definition, to range such clearly instinctive reactions as fighting, constructiveness, self-display, which with their associated affects are as much concerned in preserving the individual as in preserving his species. Nor will I do more than point out in passing that the apparent opposition between preservation of the individual and preservation of his species is biologically unjustifiable. The two are inevitably inter-dependent, otherwise their respective efficiencies would suffer. Freud is not any happier by his classification of instincts elsewhere into life- and death-instincts, the former making for the preservation of the species, the latter heading for the death and disintegration of the individual, but becoming sublimated, through the agency of the life-instincts, to the "will to power" and cruelty.

Were Freud pressed with the objection that suckling is not a sexual but an ego (or self-preservative) instinct, he would retort (as he has indeed said) that it is only later in the life of the individual that sexual instincts are detached from the self-preservative instincts, as—he would say—the stage of auto-erotism (by which he only means interest in the self) passes to the love of (by which again he means merely interest in) external objects. Elsewhere Freud even suggests that all instincts are qualitatively identical. But such a reduction of instincts to an unknowable common origin is, at best, only of philosophical interest and is surely most improbable.

### THE LIBIDO.

The Freudian doctrines are fundamentally derived *from the supposition* that all "wishes" and "desires," by which is psychologically meant all conative activities, of any importance, are dependent on the exercise of the sexual instincts, and that the energy of the whole mental and nervous system is like a fluid which can be dammed up and drained, now in one direction, now in another. I know of no adequate psychological or neurological evidence in support of this view. Freud employs the term "libido" to designate the force by which the sexual instincts achieve expression. Only the sexual instincts have *libido;* the self-preservative instincts have to be content with ego-*interests*. The libido is never changed, we are told, into ego-interests. Whether, and if so how, the ego derives its activities, save from those of the instincts which it controls, is left unsaid. Sometimes the libido seems to be an innate instinctive force incessantly battling with the ego. Sometimes it is obscurely described as the investment of energy directed by the ego; at others—e.g., in auto-erotism—as inflating the ego with its own energy. Sometimes, as in anxiety, the ego is described as flying from its libido; at others as censoring and blocking the discharge of the libido, which is thus withdrawn to as a subconscious. Sometimes the ego is regarded the great reservoir from which the libido flows out and returns.

[14] Introductory Lectures on Psycho-analysis, pp 263, 204.

## THE "PLEASURE PRINCIPLE."

Such fantastic creations are by no means the sole components of Freud's superstructure which the psychologist must oppose. His belief that pain is associated with increase of excitation and with the damming up of energy, whereas pleasure is associated with opposite processes, is obviously not in full accordance with the facts. His belief that the infant only responds to the "pleasure-principle" and that only later does it follow the "reality-principle," is equally unacceptable. In the first place, it is untrue to suppose that the primary motive of action is the search for pleasure. Pleasure maintains action and re-establishes a situation; it does not originate action. Secondly, from its very birth the infant is brought to face reality. It cannot suckle just when it likes, it has to submit to the regular routine of toilet, it is put to sleep and awakened at regular hours. There is no stage in its extra-uterine life when it can be said to obey one of the two so-called principles without obedience to the other.

## THE UNCONSCIOUS AND THE SUPER-EGO.

In his justifiable efforts to endow the unconscious with characters different from, and more primitive than, those of the conscious, Freud has practically identified the unconscious with the sexual libido and has urged that both act irrationally merely according to the pleasure principle. Of late, however, he has seen the necessity of withdrawing from this attitude. Contrasting the ego with the "*es*," as he now calls it—i.e., the conscious self with the unconscious—Freud has been forced to posit an ego-ideal or a super-ego; in other words, a moral factor dominating the ego, a voice of conscience above the ego, which exercises the same functions as the unconscious censorship (in the "preconscious") exercises on dreams. He has now come to recognise the existence of an "unconscious conscience"—apparently an unconscious state of the super-ego. Indeed, he supposes that the *es*, or unconscious, is the source of the super-ego, although in the service of the super-ego the ego comes into conflict with the *es* in overcoming the Œdipus complex. He also suggests that the super-ego, or conscience, acquires its characteristics of authority and affection, because it is created by the first relations of the libido of the *es*—namely, towards the two parents—when "introjected" into the ego.

Who but a blind follower, totally untrained in psychology, could adopt such a wild, useless farago of generalisation? Freud sees sex everywhere, and attends to little else. Morality arises from the Œdipus complex; speech is perhaps derived from sexual communication; suggestion is dependent on sexuality; obstinacy, meanness, and orderliness in adult life result from the holding back of stools in infancy; intense burning ambition occurs among those who formerly suffered from enuresis!

## THE ABUSE OF SYMBOLISM.

It is as easy to deny all this *in toto* as to accept it *in toto*. There are few statements of Freud which are wholly untrue. But his lack of psychological training, the need to maintain his position as the head of a school and his own brilliant and erratic personality, combine to make his teachings ridiculous in the sight of all free-minded men. Let us take, as a further instance, Freud's exaggerated reliance on symbolism as a means of interpretation. Who can deny that symbolism often provides a source of escape from, a substitute for, unwelcome ideas? But let us examine the list of symbols given by Freud for the genital organs. For the male organ, the symbols include sticks, umbrellas, poles, trees, knives, daggers, sabres, guns, revolvers, taps, watering-cans, springs, telescopes, nail files, hammers, balloons, aeroplanes, reptiles, fishes, hats and cloaks, machinery, keys. For the female organ, the list comprises pits, hollows, caves, jars, bottles, the mouth, ships, pockets, cupboards, chests, rooms, windows, doors, gates, wood, paper and all other materials, together with objects made therefrom, snails, mussels, churches, apples, peaches, and other fruit, landscape with rocks, gardens, and flowers, jewel cases, and shoes. And these lists are admittedly not complete! With such a vast choice of symbols, what dreams in a normal person, what associations in a case of psychoneurosis cannot be given and assured a sexual significance, when once the analyst has made up his mind to find it?

Is it conceivable that different analysts, laying different stresses on the relative importance of the Œdipus complex, the castration complex, the death instinct, the desire for re-birth, the love of mastery, the play of purposive, prospective functions—all accepted in greater or less degree by the Freudian school of to-day—will independently give the same interpretation to the same dream or symptom? That the interpretation satisfies the dreamer or patient is, I repeat, no proof of its accuracy. A man may be convinced of sin without having actually committed it. Days, weeks, or months of daily intimate intercourse with a psycho-analyst, and the increasing influence and prestige (in Freudian language, transference) which he exercises over his subject will lead the latter to accept any system of explanation as satisfactory and correct.

## THE PLAY OF SUGGESTION AND CONVICTION.

Those who wish to see to what lengths Freud and his followers are prepared to go in bringing such suggestion to play on their subjects should read his published "Analysis of a phobia in a 5-year-old boy."[15] So innocent Freud seems of the dangers of suggestion that he can write: "If I say to you 'Look up at the sky and you will see a balloon,' you will find it much more quickly than if I merely tell you to look up and see whether you can see anything."[16] Freud observes that "an experienced physician does not meet his patients unprepared and, as a rule, asks of them not elucidation but confirmation of his surmises."[17] In other words, the psycho-analyst is so certain of his own interpretation of the patient's revelations that his main task is to convince the latter of the truth of them. "Denial at the beginning," says Freud, "should not mislead the physician; every resistance is finally overcome by firmly insisting on what has been inferred and by emphasising the unshakable nature of one's convictions."[18]

Surely this attitude is the explanation of Freud's earlier insistence that "an infantile history of seduction by adults or other older children" was characteristic of, and chiefly, if not wholly, responsible for subsequent psychoneuroses. A few years later Freud had to admit that many accepted histories of such early seduction were found by him to be purely fictitious and imaginary. Is it not likely that Freud's conviction, based on a few possible real instances, led him to suggest (no doubt quite unconsciously) to his hysterical patients that they had been violated in early life and that these patients had finally accepted the suggestion? But Freud is satisfied with relating such seduction phantasies—as they turn out to be ("memory romances," as he calls them [19])—to the repressed memories of other infantile sexual experiences on which they were founded and to the hysterical symptoms into which these had become transferred.

[15] Collected Papers, vol. iii., pp. 149–289.
[16] Introductory Lectures on Psycho-analysis, p. 365.
[17] Collected Papers, vol. i., p. 224.
[18] Ibid., p. 228.

Members of the psycho-analytical school are equally subject to suggestion, when it assists their faith in their master To my own knowledge a purely fictitious dream was jokingly related in all seriousness to one of the ablest of Freud's followers. He immediately assumed that it was true and proceeded to interpret it in the light of sexual symbols, just as a servant girl might do by consulting her dream-book. So convinced was he of the truth of the dream and its interpretation that he published it in one of the many able essays he has written in defence of the Freudian position!

Take such a dream as the following, offered by Freud, as an example of symbolic interpretation: "*The dreamer met his sister with two friends who were themselves sisters He shook hands with these two, but not with his sister*" We are told that there was an actual episode connected with this in the dreamer's mind. Left to free association, his thoughts passed (under the influence of how much suggestion we can shrewdly guess!) "to a time when his observations led him to wonder why a girl's breasts are so late in developing The two sisters, therefore, stand for the breasts; he would have liked to grasp them with his hand, if only it had not been his sister."

Or take the following dream: A woman who had been married for ten years dreamed about herself, her husband, a friend of about her own age and her fiancé to whom she had just become engaged Freud interprets this dream to mean regret on the part of the woman for having married so early, had she waited she might have done better. He admits that the dream offered no association justifying this conclusion! "...the dreamer had not been aware that she had such disparaging thoughts about her husband; she did not know why she should so disparage him" But "there occurs to us almost spontaneously," says Freud, "the following [i.e, the above] construction of the latent dream-thoughts for which the manifest dream is a highly-distorted substitute"! Why? Because in the dream "references to time are noticeable at several points"; action is "taken too soon and in too great a hurry." "*Going to the theatre* obviously stands for marriage. *Getting the tickets too soon* is, in fact, a direct substitute for 'marrying too soon,'" because after marriage a woman can see things at the theatre which are forbidden to the unmarried girl! [20]

We need no further illustrations of the fact that the psycho-analyst is so convinced of many of his interpretations that he feels no necessity to consult his subject. He has no hesitation even in revealing the innermost thoughts and unconscious "wishes" in the lives of dead and imaginary characters, Leonardo da Vinci, Hamlet, and others.

## Freud's Contributions to Psychology

Let it not be supposed that Freud's labours have been in vain and that we must reject all his work because we refuse to accept his wild, unfounded generalisations. No one has done more valuable service than he in insisting on the dynamic conception of mental processes and on the importance of early experiences alike in the education of the normal adult, in dreams, and in the neuroses. He has rightly stressed the principles of fixation and regression—i e, arrest during development and return to an earlier phase of development—for the light they throw on many mental disturbances. He has greatly advanced psychotherapy by emphasising the enormous influence of repression and censorship and the importance of symbolism. His analysis of the processes characteristic of the dream are of special value,—his description of how the dream is determined by condensation, displacement, secondary elaboration, regression, opposite meanings, prominence of visual imagery, &c.

Most people would probably credit Freud with definitely establishing the existence of unconscious mental processes He himself finds "incontrovertible proof of the existence" of the unconscious—because, forsooth, psycho analysis "works" and because we need it as an explanation [21] But we must remember that a hypothesis may still remain a hypothesis, however valuable it may be I do not myself see how the existence of unconscious mental processes can ever be *proved*. Some reject the unconscious mind because they regard it as inconceivable But if the notion that it conveys works better than any other, we have as much right to employ it as the physicist has to credit the ether with equally inconceivable characters.

Despite our agreement with Freud in his distinction between "preconscious" and "unconscious" processes, we may justly criticise him for his familiarity with the latter. He claims to know as much about the nature of the unconscious mind as the ordinary religious man claims in regard to the mentality of God. Anthropomorphism in religion is hardly less justifiable than what may be correspondingly termed "egomorphism" in psychology. If nothing is more certain than that the "mental" processes in any existing ultra-human purpose and direction must be quite different from our own, and that it is therefore absurd to speak of God's feelings, wishes and motives in human terms, we must also realise the impossibility of speaking, as Freud does so confidently, of unconscious ideas, unconscious wishes, and the like in terms of consciousness If only Freud had taken the trouble to define more adequately what he meant by wishes, by ideas, and indeed by sexuality, instinct, anxiety, love, and other terms, and if only he had endeavoured to abide even for a few consecutive years by these definitions, how different would have been the result! But we should have exchanged the wild visionary, the inspired seer, for the duller, more temperate man of science.

Let us, then, not part from our subject without giving Freud his due. In him we recognise a great genius who has contributed vastly to the advance of psychopathology, but whose inspirations have been tainted by his peculiar temperament and have not been adequately controlled by critical intelligence and by a knowledge of normal psychology. A brilliant theory, even if it be wrong and impossible, has a stimulating influence in arousing opposition and in encouraging the discovery of new facts that will refute it. The pity is that its acceptance is often so wrapped up with suggestion, faith, and worship that an appeal to reason becomes ineffective.

---

**Royal London Ophthalmic Hospital.**—The chief facts recorded in this year's report are, first, that plans have been drawn up to build the extra nursing accommodation required (these have met with the approval of King Edward's Hospital Fund and £2500 towards the £10,000 needed has already been collected); secondly, that this was the first hospital to be equipped with a wireless installation by the *Daily News* fund; and thirdly, that the hospital is indebted to the Medical Research Council for its gift of a mercury-vapour lamp by means of which artificial sunlight treatment is now being provided for those cases likely to derive benefit. This has proved a valuable addition to the resources of the hospital, as was apparent from papers read by Mr C. Goulden and Dr W. S Duke-Elder at the annual congress of the Ophthalmological Society held recently.

# THE PATHOLOGICAL ACTION OF LIGHT UPON THE EYE.

BY W. STEWART DUKE-ELDER, B.SC.,
M.D. ST. AND., F.R.C.S. ENG.,
PLUMMER RESEARCH FELLOW IN PATHOLOGY.

*(From the National Institute of Medical Research and the Ultra-Violet Clinic, Royal London Ophthalmic Hospital.)*

## PART II.*—ACTION UPON THE LENS: THEORY OF THE GENESIS OF CATARACT.

SINCE Brisseau, in 1705, first drew attention to the fact that cataract was nothing more than an opaque lens, a very large amount of work and a still larger amount of speculation have gathered round the cause of the formation of the opacity, but it is only of recent years that the fundamental aspects of the problem have been approached. From time to time light and heat have been stigmatised as the cause of one or other of the forms of this disease, often on somewhat indirect and circumstantial evidence. The main cause of the popular rejection of this hypothesis would appear to be the comparison of the dramatic effects produced in the test-tube or in the laboratory animal with the gradual process which occurs clinically, and a failure, until recently, to consider the more intimate beginnings of the process instead of the gross end-results. In a comprehensive theory of the genesis of cataract it would seem that, with certain exceptions to be pointed out later, the fundamental cause of cataract in all its forms may be traced to the incidence of radiant energy directly on the lens itself.

Although recognised as of different nature because they are appreciated by different receptor mechanisms, and although embracing phenomena apparently so diverse as light, heat, and chemical and electrical effects, the whole of the energy spectrum is of fundamentally identical character, believed to be electromagnetic vibrations travelling in the hypothetical ether, differing only in the length, frequency, and amplitude of their waves. All radiations transfer energy to the substances which absorb them; the longer waves by increasing molecular movement produce primarily a thermic effect, the smaller ones, whose frequencies correspond to the intra-molecular oscillations, by increasing atomic motion, induce direct atomic disintegration with consequent photochemical and photo-electrical effects. Every substance absorbs radiant energy to a greater or less degree, and its reaction to that energy is in the last analysis identical, and is dependent upon this absorption, whereby energy is transferred to its molecules or their parts with the result that they are shaken apart. Apart from this there is no evidence of any specific action peculiar to any wave-length.

### 1. *The Radiant Energy Affecting the Lens.*

In order to reach the lens incident radiant energy must first traverse the cornea and the aqueous, and since the first of these is the more absorbent, the nature of the radiations to which the lens is exposed is determined by the transmission of this structure. The transmission of the cornea in the mid-spectrum has already been discussed in the preceding article; in addition, like all living structures, it is transparent to the very long and the very short wave-lengths at either extreme end of the known spectrum. For all practical purposes it may be taken that the lens is reached by incident radiation of wave-lengths of the order of $10^{10}$ Angström units (electrical oscillations), those in the region 20,000 to 3000 (short infra-red, visibles, and long ultra-violet), and those of the order of one A.U. (X rays, gamma rays).

Having reached the lens one of five things may happen to the energy represented by these rays. It may be (1) absorbed into the energy system of the lens, causing changes therein; (2) transmitted according to the laws of refraction, without affecting the lens; (3) dispersed by the particulate structures in the lens, whereby its path is changed; or (4) it may induce fluorescence; while (5) a small fraction is reflected from the surfaces.

It is with the absorbed portions of the incident energy that we are primarily interested in the consideration of its possible pathological effects upon the lens, since only these can exert an effect, deleterious or otherwise, upon it; and those rays between 20,000 and 3000 will concern us most, inasmuch as the spectra of all ordinary sources lie between their limits. At the upper end of this region, in the infra-red, the percentage absorption has been investigated by Hartridge and Hill, whose results corroborate the earlier conclusions of Aschkinass and Vogt. Above 20,000 A.U. no rays, and above 14,000 A.U. practically no rays get through the cornea; from 13,500 to 11,000 the lens absorbs about 25 per cent. of the incident energy; thereafter, apart from a band at 9750, it is to all intents and purposes transparent, especially from the commencement of the visible spectrum until we come to the long ultra-violet at 4000. A very large number of experimenters have made determinations of the limit of transmission and the commencement of absorption in this region, and it has been established that in the normal adult absorption in quantity begins at 4000 and is largely complete at 3500 (Parsons, Martin), although transmission is slight down to about 3200 (Shoji, Glancy). The limits vary considerably, however, with age and with the amount of pathological sclerosis present; thus, in the young the lower limit is 3055 (Shoji) or 3100 (Schanz), in the aged the upper limit is frequently 4200 (Hallauer), while in the cataractous lens absorption is marked well within the violet—4400 (Graham). In both cases this rise can be correlated with a corresponding rise in the absolute and relative albumoid content of the lens, which substance, being the most strongly absorbent of its constituents, largely determines the absorption of the whole.

In the average normal adult, therefore, a large proportion of the rays between 14,000 and 11,000, and between 4000 and 3200, and practically all the rays between 3200 and 3000 are absorbed; those of the first two spectral regions will produce a potentially pathological thermal effect, those of the third will produce an abiotic effect as well as a mild thermal one. The fact that abiotically active rays are so absorbed is seen in the observations of Schulek and Birch-Hirschfeld, who found that an exposure to ultraviolet, which in the normal rabbit left the retina unaffected, produced typical abiotic changes in the retina of the aphakic rabbit.

A considerable amount of transmissible light is dispersed in its passage through the lens—a Tyndall effect. Van der Hoeve (1918) showed that the lens is an optically heterogeneous substance, in which solid particles, many of them in Brownian movement, can be seen on dark-ground illumination. Light is dispersed from these particles, partly polarised, but with its wave-length unchanged. The short waves are most affected in inverse proportion to the fourth power of their wave-lengths (Rayleigh's law)—i.e., 16 times more ultra-violet of wave-length 4000 will be dispersed than infra-red of 8000. This deflection of the shorter waves accounts in part for the protective function of the lens over the retina observed experimentally by Birch-Hirschfeld, but since the wave-lengths are unchanged it can have no pathological action on the lens itself apart from the action of the incident light, except in so far as its path in the lens is lengthened, and the amount absorbed will, therefore, be proportionately increased.

Fluorescence is a phenomenon whose intimate nature is little understood. When light passes through a fluorescing substance the particles of the substance become light sources themselves, emitting light of wave-length different from that of the incident light, preponderatingly longer, but also shorter. Measuring by Newton's method of crossed spectra, Schanz (1909) found the region of maximum fluorescence in the lens to be from 3500 to 4000. The effect of this phenomenon is regarded differently. Considering that its production implied absorption, Schanz looked upon it as deleterious; in any case, any shorter waves so produced will be more easily absorbed. On the other hand, from the work of Burge (1915), who correlated a decrease of fluorescence with an increase in the coagulability of lens proteins, it is probable that it may be looked upon rather as a protective mechanism, whereby active short waves, which might induce coagulation, are changed largely into long (visible) waves which are less active, by which means their energy, being in a more transmissible form, is the more safely got rid of.

* Part I. appeared in THE LANCET last week.

### 2. *The Concentration of Radiant Energy in the Lens.*

From a pathological point of view the concentration of incident radiant energy in its passage through the lens is of primary importance. Two opposing factors are at work: a concentrating effect due to refraction by the optical system of the eye, and a dissipating effect due partly to the specific absorption of the media and partly to irregular loss incurred by reflection in passing between media of varying refractive indices, by dispersion in passing through the substance of optically heterogeneous media, and by spherical and chromatic aberration. The loss can be calculated with fair exactitude. With regard to the first factor there is no specific absorption by the media of the eye apart from that due to a dilute watery solution of protein, whose magnitude has been calculated by Aschinas (1896), Luckiesh (1913), and Hartridge and Hill (1915). Most of the energy is absorbed in the anterior part of the eye, the absorption rapidly decreasing exponentially as the depth of the layer increases. The loss by general dispersion may be taken as 10 per cent. of the incident energy.

The total density of energy in the lens depends further upon the size of the pupillary aperture and the size of the illuminating source. For small and intense radiants, such are used experimentally and clinically, the source may be taken as of constant area corresponding to the circle of diffusion, and the intensity of energy concentration varies as the inverse square of the distance from the eye (Charpentier). For sources subtending a relatively small solid angle there is a uniform mean energy density throughout more than half the path through the eye (Luckiesh), since the absorption and dispersion of energy in the media counteract fairly exactly the concentrating effect of refraction; for these sources, there is, therefore, no serious concentration in the lens. But for sources of large extensity the distribution is widely different, since the ratio of energy density just behind the pupillary region varies approximately as the solid angle subtended by the source. Thus, for a source subtending the maximum solid angle of 120°, the energy density in this region is greater by several million times than with a small source—this, it is to be noted, when the energy intensity at the retina is the same, the retinal image is of the same brightness, and the spectral character of the illuminant and the intensity of the illumination are the same. Thus, while a source of small area, as is used experimentally, may be harmless, a similar large area, as the sky, a snow-field, the desert, or a sheet of molten glass or metal entails an enormous energy concentration in the region of the lens. This is a consideration which has been largely overlooked in the interpretation of experimental work undertaken to elucidate the pathogenesis of cataract.

### 3. *The Pathological Action of Radiant Energy on the Lens.*

(1) *Action on the Lens Capsule.*—The longer wavelengths produce a thermal action on the lens capsule which can readily be obtained experimentally. Tissue death is induced by coagulation of the proteins, with subsequent exfoliation of the cells.

When in sufficient intensity, the shorter wavelengths produce a typical abiotic effect (Hess, 1909; Martin, 1912; Verhoeff and Bell, 1916). This is not obtained unless a critical exposure is given, since with great intensities of radiation the cornea turns opaque and protects the underlying structures, while with lesser intermittent exposures the factor of physiological repair in the time interval comes into play. After short exposures swelling of the cells is the only change noted; further intensities involve the appearance of the typical eosinophilic and basophilic cells associated with abiotic reaction; more prolonged and intense exposures induce nuclear pyknosis. Round the periphery of the exposed area, just underneath the pupillary margin, there is a zone of cellular proliferation surrounded by an area of marked karyokinetic activity. This has been variously explained as being due to compression of the marginal cells by the central swollen cells (Hess), which cannot readily explain the nuclear activity; to stimulation due to submaximal damage (Martin), an assumption difficult to accept since no short waves can penetrate the iris overlying the affected area; and to the action of toxic substances diffused from the injured iris cells (Verhoeff and Bell), which does not explain its strict localisation. In all probability the changes are due to stimulation of cellular activity by the heat which is absorbed in quantity by the iris pigment, which in this region comes into direct contact with the lens capsule.

(2) *Action on the Lens Substance.*—The action of radiant energy upon the lens substance is to produce opacity, or so to increase the lability of its colloidal system that the formation of opacity is more easily produced by other influences. Since the fundamental happening in the formation of the opacity of cataract is the coagulation of the lens proteins, a brief résumé of their nature and their reactions is essential to the understanding of the problem.

*The Lens Proteins.*—These have been investigated by Laptschinsky (1876), Morner (1894), and more recently with more refined methods of purification by Jess (1913). They are four in number: (*a*) "albumoid," a water-insoluble protein found especially in the nucleus; two water-soluble proteins found especially in the cortex—(*b*) α-krystalline, mainly in the outer cortex, and (*c*) β-krystalline, mainly in the inner cortex; and (*d*) albumin in small quantity.

Throughout the body generally active metabolism is closely associated with the presence of cystein-containing proteins; this amino-acid is found in large amount in β-krystalline, in less amount in α-krystalline, while the "albumoid" contains practically none. Correspondingly, with age the insoluble protein (albumoid) increases and the soluble proteins (krystallines) decrease (Jess, 1920); this process is thus accompanied by a gradual and parallel diminution of the cystein content of the lens with advancing years (Goldschmidt, 1917). A similar process occurs in cataract, where combined cystein may be partially or completely absent, while the albumoid content is increased (Jess; Reis, 1912). It is to be noted that the whole of the SH-reacting compound is not bound up with protein; a part of it is dialysable (Abderhalden and Wertheimer, 1922), which part has been recognised by Goldschmidt (1924) to be glutathione.

*The Lens Metabolism.*—Both physiologically and pathologically the lens is a sluggish tissue, but to live and to maintain its transparency it must possess a metabolism, which involves primarily a respiratory mechanism. The presence of this mechanism has been definitely established and the oxygen up-take measured (Adams, 1925). Throughout the body there are two main types of respiratory mechanism—an external one whereby respiratory gases are mediated directly by the blood stream, and an internal one, recently elucidated by Hopkins, whereby a balanced autoxidation mechanism is maintained in a constant chemical equilibrium by an oxidation-reduction system of an SH<—>SS type. Loeb Cascio (1922) claims to have demonstrated the presence of oxidases and catalases in the lens, but, while these may have a secondary activity as in the oxidation of certain fatty acids (Ahlgren), it is practically certain from the work of Goldschmidt (1924) and Adams (1925) that the internal metabolism of the lens is carried on by an autoxidation system wherein glutathione acts as a hydrogen donator, which reduces the hydrogen acceptors, and $\beta$-krystalline acts as a thermostable residue which reduces the glutathione after it has been oxidised. The lens is an avascular structure, and this internal system, which in other tissues is of secondary importance, presumably becomes here the central fact in metabolism, and if it is destroyed or partially put out of gear it would seem to follow that the transparency of the lens must suffer. Accordingly, we should expect to find, as Goldschmidt (1924) claims to have demonstrated, that the normal lens has a higher glutathione content than other tissues and that corresponding with the decrease in cystein—i.e., krystalline—content with increasing age, the reduction power also decreases. Similarly, in the cataractous lens, which is poor either in cystein or in glutathione or both (Adams), the reducing power decreases with the state of maturity. Running parallel with these changes, we have already noted the increase of absorption of light by the lens in these two conditions; while, connecting the two sets of phenomena, Adams has shown that the glutathione content, and therefore the metabolic efficiency of the lens, is lowered considerably after exposure either to heat or to ultra-violet rays.

The so-called "lipoid substances" (phospholipins, sterols, &c.) in the lens probably have some effect on the working of the autoxidation system by increasing the rate of oxidation (Meyerhof, 1923). It is significant that, according to the findings of Goldschmidt (1922), these substances are at a minimum about the decades 40 to 60, and that in the cataractous lens they are withdrawn from solution, and therefore from activity, and deposited as crystalline or amorphous particles (Valetin, 1919), which may be macroscopically evident.

*The Coagulation of Protein.*—According to the most recent ideas, proteins may be changed from the colloidal to the particulate form by two distinct processes: precipitation and coagulation. Precipitation, which is brought about by the action of concentrated salts as ammonium sulphate or by alcohol, is a reversible and purely physical change whereby aggregates of chemically unchanged particles are thrown out of colloidal solution in a condition capable of reversion to their original colloidal state; with this we are probably not concerned in the development of cataract. Coagulation, on the other hand, is a complex process which takes place in two stages: (1) denaturation (Chick and Martin, 1910), whereby the natural protein is chemically altered to a form in which it is readily coagulable; (2) agglutination, a physical process whereby coagula are formed by flocculation of the denatured particles.

The intimate nature of the primary chemical change of denaturation is not yet cleared up. Chick and Martin conclude that it is a reaction between the natural protein and water. This, according to Pauli (1910) and Robertson (1911), is a dehydration, involving the formation of an internal anhydride by the elimination of $H_2O$ between the terminal $NH_2$ and COOH groups of the protein chain, with a possible tautomeric keto-enol transformation in the peptide linkages. Harris (1922), however, has brought evidence to show that it is more probably a hydrolysis involving the production of a sulphydryl group from the thiopeptide linkages. In the development of cataract a considerable amount of hydrolysis of this type takes place, since in the aqueous of cataractous eyes deposits of tyrosine seem to be frequently found (Burdon-Cooper, 1914), while the pigment found in the so-called "black cataract" is melanin, an oxidation product of tyrosine (McHardy, 1882).

From the point of view of this thesis there are three aspects of this reaction that are of especial interest: the factors causing it, its time relations, and the influences which may aid or accelerate its development. Coagulation appears to be brought about under suitable conditions by any form of radiant energy, and, moreover, by mechanical stress. The most common and best known form in which this energy is received is heat (Chick and Martin); visible light also brings it about (Young, 1922); coagulation is also induced by ultra-violet (Dreyer and Haussen, 1907; Bovie, 1913; Clark, 1922); and by radium (Dreyer and Haussen, 1907; Fernan and Pauli, 1915). In the case of the shorter wave-lengths the primary action of denaturation is not identical with that caused by the longer heat waves. Thus in place of the high temperature coefficient which characterises the reaction to heat, denaturation following exposure to ultra-violet light, like other photochemical processes, has a very low temperature coefficient. In the last analysis, however, both are identical, and the second process of agglutination is never photochemical, but is a spontaneous consequence of the thermal or photochemical denaturation which precedes it. Coagulation is further produced by energy imparted to the molecules of the protein by mechanical shock, such as agitation, or by the application of any undue strain, as on the surface of expanding air bubbles or any marked double phase such as is produced in the mixing of two immiscible liquids, or the application of great hydrostatic pressures (Bridgman, 1914). As will be seen, all these forms of energy may be correlated to form a comprehensive theory of the development of cataract in its many clinical forms.

The time factor in the process of coagulation has often been brought forward as an objection to any theory of cataract formation by the direct influence of radiant energy. On comparing the coagulation of proteins in the test-tube or the experimental production of lenticular opacity in the laboratory with the extremely slow and gradual development of the usual forms of cataract, and even of such forms as glass-blowers' cataract, it has been felt that the difference in time puts the two in entirely different categories, and has led to the theory at present generally accepted—of indirect malnutrition. Such an objection, however, does not take cognizance of the chemical nature of the processes involved. Chick and Martin have shown that the process of denaturation is a chemical process of the monomolecular order, and that upon it the effect of temperature is merely acceleratory. According to these observers, it is an orderly time-process, influenced by temperature according to a logarithmic law which is represented fairly exactly by the equation of Arrhenius, and the so-called "coagulation temperature" of various proteins merely depend on the extremely high temperature coefficient (1·91 per 1° C. for albumin) possessed by the reaction. With rising temperature a critical point is reached at which the energy supply is sufficient to impart a velocity capable of completely overcoming the existing forces tending to stability, and the reaction, hitherto slow, suddenly becomes so rapid as to appear almost instantaneous. Incident energy, therefore, in the form of heat, light, &c., in sufficient intensity acts as a catalyst to the chemical action of denaturation, without which it would proceed infinitely slowly. On this ground alone the time objection is rendered invalid.

There is, however, another factor which probably is of more importance. The two processes of denaturation and agglutination which together constitute coagulation are distinct, and while under the usual experimental conditions they occur practically simultaneously, they may be separated by a time interval of theoretically infinite duration. The influx of radiant energy may induce denaturation and induce it over a very long time interval, and the denatured protein may then remain unagglutinated, leaving the medium of which it forms part transparent until such time as suitable conditions induce flocculation and consequent opacity. It is here in all probability that any influence of malnutrition may play a part in cataract formation as a secondary factor. Thus Mond (1922) has shown that after ultra-violet radiation, such as will not produce coagulation, proteins show definite physical and chemical changes, and exhibit a decrease in stability, becoming more labile and more readily coagulable by various agencies. Correspondingly in the lens Burge (1910) claims that if a lens, after exposure to ultra-violet radiation which left it still clear, be immersed in certain salt solutions of concentrations which left the normal lens unaffected (0·1 per cent. CaCl) it turned opaque. The clear and apparently unchanged lens is therefore modified in such a way by radiation that its proteins are readily coagulated by small changes in the salt concentration of the medium in which it lies. An analogous clinical occurrence is the fact that in India, where the eye is exposed to excessive solar radiation and where cataract is common, the lens while yet apparently normal frequently is darkly pigmented with melanin (see Collins, 1925), an oxidation product of the hydrolysis of protein. These considerations may be compared with the significant observation of Adams (1925), that after exposure to heat or ultra-violet radiation the lens, while yet clear, showed a decreased glutathione content. These two considerations should be viewed in the light of the fact that in the lens, possessed as it is of a very sluggish metabolism, the factor of physiological repair will not come into play as evidently as in a more active tissue, and slight degrees of submaximal damage will therefore tend to become largely additive.

The main factors influencing the incidence of coagulation are the concentrations of salts and hydrogen ions. The primary reaction of denaturation itself involves a change of reaction depending on the pH of the medium, and the maximum rate of agglutination of the denatured protein occurs at the iso-electric point (Sörensen, 1911; Michaelis, 1911), because the state of dispersion of the particles is due to their mutually repulsive electric charge, which at the iso-electric point is neutralised. Correspondingly, Goldschmidt (1924) found that the reducing power of the lens was very sensitive to changes in reaction, disappearing if the medium was more acid than pH 7·0. He suggests that the most probable cause of all cataract other than traumatic is a gradually rising hydrogen-ion concentration, thus upsetting the autoxidation system. But the pH of the aqueous appears to be fairly constant at 7·3 to 7·5 (Meesman, 1924; Hertel, 1921), and in cataract it has been invariably found to be alkaline (Burdon-Cooper, 1914). In the rabbit the pH of the two is the same, and with an alkaline aqueous an acid lens is at any time unlikely; while, therefore, it would seem improbable that the reaction is of primary importance, its influence as a secondary factor is undoubted. Thus, for example, Hertel (1921) found in a case of diabetic coma a pH as low as 7·02 in the aqueous.

The other secondary factor of great importance is the salt concentration. In the process of agglutination the electrolytes act by altering the reaction of the protein-containing medium, or by neutralising or increasing the electric charge carried by the protein particles according as the charge on the protein is of similar or opposite sign to that carried by the more potent ion of the salt. Schanz (1915) found that the addition of salt to pure protein increases its power of absorption of light, and the great effect of the presence of salts, particularly calcium salts, upon the formation of lenticular opacity by ultra-violet light found by Burge has already been alluded to. In addition, other substances seem to have a similar sensitising effect on coagulation by light, the most interesting of which are glucose and acetone (Schanz, 1915; Young, 1922).

Apart from this influence in association with light, salts can have no direct precipitating action on the lens protein in vivo, since they could never accumulate in sufficient concentration. Thus it requires a 2·25 per cent. solution of calcium salt (Nelson, 1923) or 6 per cent. of glucose (Deutschmann, 1887) to induce opacity in the lens. They have, however, a further and very important influence in determining osmotic change. The lens, surrounded by its capsule, forms a separate physico-chemical system from the aqueous. Its chemical composition is widely different, while its osmotic value is equivalent to a 1·2 per cent. solution of NaCl (Manca and Ovio, 1898), whereas that of the aqueous is equivalent to a 0·9 per cent. solution. Owing to the tonic pull on the capsule by the ciliary muscle the internal tension of the lens is kept at a higher level than that of the aqueous, and, therefore, while fluid may pass out by filtration and diffusion, it can only enter by osmosis. To form an intelligent picture of the maintenance of the intra-vitam equilibrium we must postulate some forces acting after the manner of a semipermeable membrane, and work must constantly be being done by osmosis acting against the filtration pressure induced by the tonic pull of the ciliary muscle. That this mechanism is the lens capsule is seen by experiment, for on damaging it experimentally (Hess, 1887), or in the operation for the maturation of immature cataract, or on rupturing it as in needling, the lens behaves as does the dead lens—it puts on weight by the addition of aqueous, swells, and turns opaque. The normal mechanism is therefore deranged and aqueous will enter (1) if the difference between the osmotic pressures is increased; (2) if the internal tension of the lens is lowered or the intra-ocular pressure is increased; (3) if the vitality of the "semipermeable membrane" is lowered or its continuity broken.

The first will occur in certain diseased states as diabetes; the internal tension will fall with the loss of elasticity of old age; an increased intra-ocular pressure may act in absolute glaucoma; and the membrane is ruptured in trauma, while its vitality is lessened in debility and nutritional deficiences or under the action of light. This last does not necessarily depend on any gross pathological change such as we have noted to be produced by the massive radiation of thermal or actinic rays, but would appear to be a very widespread physiological phenomenon in nature. In its effect on the turgor of plants it is responsible for heliotropic curvature. In its preferential permeability the lens capsule resembles closely the red blood corpuscles; the potassium content of the lens is said to be 38·8 per cent., of which 0·6 per cent. is in solution as KCl, while in the aqueous there is the merest trace (0·03 per cent.) of this element. the potassium content of the corpuscles is 0·425 per cent., that of the serum 0·02 per cent. Ultra-violet radiation changes the "permeability" of the red cell and induces hæmolysis. The percentage of total potassium falls in the lens in cataract from the normal figure of 38·8 to 9·8, according to the analysis of Burge (1909), and the loss of soluble protein and glutathione in the cataractous lens has already been referred to. Both processes are presumably to be accounted for by diffusion through a membrane of altered permeability. It is more than probable, therefore, that the shorter wave-lengths derange the "permeability" of the capsule, and facilitate the interchange of water and salts.

The mechanism of opacity formation by this agency is, in the first place, the entrance of fluid in quantity sufficient to form vacuoles between the lens fibres; these being of a refractive index different from the lens substance disperse the light, and the lens, while its fibres are still clear, appears opaque. Later and more slowly coagulation of the proteins occurs, a process in which it is probable that one or other, or all, of the following factors act—mechanical strain on the fibres inducing denaturation, comparable to the effect on the surface of a soap bubble or at the interface between two immiscible liquids, a change in salt concentration and reaction, and a diffusion outwards through the now "permeable" capsule of the diffusible substances, which include both active parts of the respiratory system—the glutathione and the β-krystalline.

*The conclusion of Part II. with bibliography will appear in our next issue.*

# A NOTE ON THE RELATIONSHIP BETWEEN DESTRUCTION OF TISSUE AND BACTERICIDAL POWER OF BLOOD.

By G. R. McCOWEN, O.B.E., M.D. McGill,
SURGEON COMMANDER, R.N.

In the course of research on the action of mustard gas on the blood of guinea-pigs and rabbits, serological experiments were carried out.

1. As regards alexin, these experiments showed that a fall occurred when guinea-pigs were subjected to mustard gas by inhalation and by subcutaneous injection. The fall of alexin was most marked in high concentrations such as 1 in 50,000 by inhalation, and also by subcutaneous injections, but less marked and transient in lower concentrations such as 1 in 200,000. It was further noted that this fall was *in no way related to the number of leucocytes,* for in these experiments any changes that occurred in the leucocyte count bore no relation to the fall in alexin.

2. As regards other antibody formation, if mustard gas be injected either before or together with antigen there is (*a*) no great prolongation of the latent period *in agglutination production, and (b) a marked restraining* influence on the production of antibodies.

3. If mustard gas be injected during the process of immunisation the restraining process is still present though lessened

4. If mustard gas be injected at the height of antibody formation the normal fall is much hastened.

In view of these findings it was thought that a measurement of the bactericidal power of the blood would give a better indication of its defensive mechanism, and this study forms the subject-matter of this article.

### *Description of the Experiments.*

The method employed throughout this research was a slight modification of that described by Sir Almroth Wright, based on research work done in collaboration with L. Colebrook and E. J. Storer and published in The Lancet.[1]

The principle of the method is to implant graduated quanta of microbes into the blood (in vitro); to introduce *the implanted blood into "slide cells"; and to incubate for* 24 hours at 37° C., to allow surviving microbes to grow into colonies. These colonies are counted against similar implantations into blood hæmolysed with distilled water (*thus destroying its bactericidal power*) and incubated at the same temperature for the same length of time; this constitutes the control. Guinea-pigs were found to be more suitable than rabbits, as the strain of staphylococcus used *was actively hæmolytic to rabbits'* blood; in addition, considerable spreading of colonies occurred, which rendered their accurate counting difficult. The blood was obtained by cardiac puncture and afterwards defibrinated, as the *employment of decalcifying agents* was found by Colebrook and Storer considerably to reduce its power to kill staphylococci and streptococci.[2]

The suspension of microbes for implantation into the blood was prepared as follows:—

A required number of unit-volumes of the recipient fluid (Ringer's fluid to which a small quantity of serum has been added) was aspirated into a capillary pipette and finally one unit-volume of a 24 hours' broth culture of staphylococcus; this latter volume was then slowly expelled on to a filter paper and finally the recipient fluid driven to the end of the pipette and expelled into a small dilution tube; by aspirating and expelling several times, the whole of the "wash" is thoroughly embodied in the recipient fluid. From this "wash" further weaker washes were prepared. For each separate test one "slide cell" with four compartments was employed.

Into the first compartment was introduced 50 c.mm. defibrinated blood + 2·5 c.mm. 1/10th wash bacterial suspension.

Into the second compartment 50 c.mm. defibrinated blood + 2·5 c.mm. 1/20th wash bacterial suspension.

Into the third compartment 50 c.mm. defibrinated blood + 2·5 c.mm. 1/40th wash bacterial suspension.

Into the fourth compartment 50 c.mm. defibrinated blood + 2·5 c.mm. 1/80th wash bacterial suspension.

As a control a similar slide contained: 50 c.mm. defibrinated blood + 150 c.mm. distilled water + 2·5 c.mm. 1/80th wash bacterial suspension. This latter bulk occupied the four compartments, and as a full complement of colonies should develop, the larger area allowed counting to be easily and accurately carried out. This method of control was verified on a few occasions by an agar count.

Three methods of exposure to mustard gas were employed: 1. By inhalation; the substance was dispersed by heat and the concentrations used were 0·07098 mg. per litre (1 in 100,000), 0·14196 mg. per litre (1 in 50,000), and 0·3549 mg. per litre (1 in 20,000). 2. By subcutaneous injections of doses varying from 10 to 88·8 mg. per kilo body-weight. 3. By application to the skin of 40, 80, and 120 mg. per kilo body-weight. This was applied within a one-inch ring to the shaved backs of three guinea-pigs.

### *Results.*

1. (*a*) After exposure to concentrations of mustard gas by inhalation, *0·07098* mg. per litre *(1 in 100,000)* and 0·14196 mg. per litre (1 in 50,000) for half an hour, it was observed that there was a tendency for the hæmobactericidal power to fall slightly 24 to 48 hours after exposure, and to rise again to normal or above after 72 hours. (*b*) After severe gassing—i.e., 0·3549 mg. per litre (1 in 20,000) for half an hour, *a distinct increase in the hæmobactericidal power* 20 hours after gassing was observed.

2. After subcutaneous injections of mustard gas in doses varying from 10 to 88·8 mg. per kilo body-weight, there is noted a distinct increase in the hæmobactericidal power within 24 hours of injection; the larger the injection the greater is the increase, *100 per cent. being repeatedly recorded after injections* of 60 to 80 mg. per kilo body-weight. It may be noted that after large doses the majority of the animals died soon after blood was taken, but this very high bactericidal power of the blood is also recorded after the same large doses in animals which survived up to 72 hours.

3. After application to the skin, the hæmobactericidal power was observed to be markedly increased after 24 and 48 hours. As in the case of subcutaneous injections, the larger the dose the more marked was the increase in the hæmobactericidal power. Detailed results of all experiments are tabulated in appendices 1–17, but not included here for lack of space.

In view of the foregoing results, experiments have been carried out with a view to ascertaining the action of mustard gas on the whole blood in vitro.

Three tubes containing 1 c.cm. of blood to which mustard gas was added in the following proportions: 1 in 1000, 1 in 2000, 1 in 5000, were incubated at 37° C. for 24 hours. The blood containing 1 in 1000 mustard gas was almost black in appearance and of the consistency of treacle; the 1 in 2000 was much less dark in appearance and less viscid; the *1 in 5000* was the least altered in colour and viscosity. It was ascertained spectroscopically that the change of colour was due to the formation of acid hæmatin. In each case the oxygen capacity was found to be much lowered. *Similar experiments carried out with 0·45 mg. of* hydrochloric acid, an amount corresponding to a third of the quantity of acid which would have been produced by complete hydrolysis of the amount of mustard gas in the *1 in 1000 concentration, gave analogous results. Implantations* of staphylococci in a medium of agar to which had been added the same proportion of mustard gas failed to develop owing conceivably to the acidity of the medium resulting *from the hydrolysis of the added* mustard gas.

Other previous experiments in which various other proportions of mustard gas were injected intravenously yielded spectroscopically no bands other than those of oxyhæmoglobin.

It is assumed that the difference exhibited by the hæmoglobin in these last experiments in vitro and those carried out in vivo can only be due to the greater action of the buffer substances in vivo. Hence, no comparison can be established and no deductions drawn. Finally, 150 mg. of undiluted hydrochloric acid were applied to the skin, and the results compared with those obtained by the application of mustard gas to the skin. In both experiments the hæmobactericidal power was found to be increased 24 hours after the application, but more so in the case of mustard gas. Further, in the case of hydrochloric acid, it returned to normal 48 hours after application, whereas in the case of mustard gas it remained at about the same level.

### *Discussion of Results.*

In considering these results, the fact must not be lost sight of that the hæmobactericidal power before gassing was by no means a constant, and was found to vary in the same animal from day to day in spite of care taken to feed and house the animals properly and to prevent them being subjected to fright, factors known to have an influence on the hæmobactericidal power. Nevertheless, the experiments show that interesting changes take place in the hæmobactericidal power after exposure to mustard gas. The tendency is for the hæmobactericidal power to increase after exposure to the concentrations used either by inhalation, subcutaneous injection, or application to the skin. In the lower concentrations by inhalation, where small implantations are employed, the hæmobactericidal power has a tendency to drop 24–48 hours after exposure, but rises again to or above normal within 72 hours; with larger implantations in the same concentrations this transient drop is very much less marked. Here might be mentioned the fact that upon making graduated implantations of living microbes into the blood, the fewer implanted, the greater the percentage of survivors, and with quite small implantations, a survival of a full 100 per cent. is often recorded. The implantations throughout this research were from moderate to large, and as far as possible uniform before and after exposure to mustard gas. In the highest concentration used for inhalation an increase in the hæmobactericidal power was recorded in all implantations, and where mustard gas was administered by subcutaneous injection and by application to the skin there is an early rise in the hæmobactericidal power in all implantations.

The above findings would appear to be contrary to those anticipated in view of the previous research carried out on the effect of mustard gas on alexin and antibody formation, and incidentally to the well-known fact that mustard gas lesions are so resistant to treatment. What, then, is the explanation of this increased hæmobactericidal power after exposure to mustard gas? The increase in the hæmobactericidal power or natural response to cope with infection or other foreign materials in the body is of a primary and secondary nature; the former makes use of phagocytic action, and where the serum is naturally bactericidal, also of serobactericidal action; the latter makes use of antibacterial elements given out by the leucocytes when these are incited by infection or other means, and it is mainly by this ectocytic chemical action, and only to an insignificant extent by phagocytosis and internal digestion, that the bactericidal action of the leucocytes is exerted.

It is considered that the increased hæmobactericidal power observed can be accounted for by the pathological findings after inhalation, subcutaneous injections, and the application of mustard gas to the skin. In the case of inhalation experiments, in the concentration of 1 in 20,000, it was found histologically that the upper air passages, the greater part of the bronchial tree, in addition to the lungs, were invaded by leucocytes in every stage of disintegration. In the case of subcutaneous injections and application to the skin the same invasion of leucocytes is seen at the sites involved, directly attributable to the intense reaction set up by mustard gas.

As stated above, it is the antibacterial elements given out by the leucocytes which constitute the hæmobactericidal power, and it is conceivable that in the course of their disintegration a considerable pouring out of these elements into the blood takes place. *Previous work has shown a fall in alexin after exposure to mustard gas*, and as no change of note has been found in the blood count, it is reasonable to assume that the origin of alexin may not be the leucocytes. Although the general consensus of opinion favours the view that the alexin is essential for the formation of bacterial antibodies, the results of these experiments do not bear out this view, inasmuch as the alexin was found to be greatly diminished.

On further consideration it was thought necessary and desirable to exclude certain possible factors which might have influenced the results obtained. 1. It was considered necessary to ascertain whether the hæmobactericidal power could possibly be affected in those cases in which the blood specimens were obtained from animals in a moribund condition.

2. Experiments were carried out with other substances causing tissue destruction to confirm the views expressed as to the cause of the increased hæmobactericidal power.

As regards (1) the following experiments were carried out:—

(*a*) A guinea-pig was given a lethal dose of amyl nitrite, and his hæmobactericidal power *at the point of death* was compared with his normal. There was no change.

(*b*) A guinea-pig was given a lethal dose of nitroglycerine and his hæmobactericidal power *at the point of death* again compared with his normal. No change was noted.

(*c*) A guinea-pig was asphyxiated by mechanical means and again no change was noted in the hæmobactericidal power at the point of death.

The reason why amyl nitrite and nitroglycerine were selected was because in neither case is destruction of tissue brought about, and further, because both these substances produce a fall of blood pressure as is the case with mustard gas.

As regards (2) the following experiments were designed with the purpose of confirming the conclusion arrived at. Those substances known to produce destruction of tissue—namely, hydrochloric acid, liquor epispasticus, and formic acid—were applied to a shaved area of skin of the back of guinea-pigs and a comparison of their hæmobactericidal power at the end of 24, 48, 72 hours, and six days made with their normal.

In the first experiment 75 mg. of hydrochloric acid were applied within two adjacent one-inch gelatin rings. In the second experiment 150 mg. of liquor epispasticus were similarly applied.

In the third experiment 75 mg. of formic acid were applied within a one-inch gelatin ring.

In the fourth experiment 150 mg. of formic acid were applied within two one-inch gelatin rings (75 mg. in each).

The results obtained showed a pronounced increase of the hæmobactericidal power within 24 hours in all cases, most pronounced in the case of the two applications of formic acid which produced the greatest amount of destruction, and only slightly less pronounced in the case of liquor epispasticus which produced least destruction of tissue.

At the end of 48 hours the hæmobactericidal power, though still much increased, showed a slight decline when compared with that present at the end of 24 hours.

At the end of 72 hours the hæmobactericidal power, though higher than normal, showed a further decline.

At the end of six days the hæmobactericidal power in the case of three animals reached its normal level, the fourth animal dying on the fourth day. The death of this animal was caused by damage produced by heart puncture in the course of obtaining blood for examination.

If, now, the blood count be considered, it was found that in every case at the end of 24 hours there was an increase of white blood corpuscles concomitant with the increase in the hæmobactericidal power. This same condition obtained at the end of 48 hours, and *pari passu* with the decline in the hæmobactericidal power there was a corresponding decline in the number of white cells. At the end of 72 hours there was a slight increase in the white count in the case of three animals, the one treated with hydrochloric acid showing a fall. Six days after the blood count exhibited no special feature and approximated to the normal.

It is not considered that the ½ c.cm. of blood withdrawn daily during the experiment affected the blood count in any way.

### *Conclusions.*

1. After exposure to mustard gas by inhalation, subcutaneous injection and application to the skin, the hæmobactericidal power has been found to increase; the more severe the exposure, the more pronounced this increase.
2. A similar increase in the hæmobactericidal power has been noted after the application of other tissue-destroying substances such as hydrochloric acid, formic acid, and liquor epispasticus.
3. No change in the hæmobactericidal power is noted at the point of death after the injection of substances which do not produce tissue destruction.
4. It is suggested that this increase of the hæmobactericidal power is due to a considerable pouring out of the antibacterial elements from the leucocytes into the blood as the result of their disintegration.
5. No conclusion is possible from a comparison of the results of the experiments carried out in vitro and in vivo for the reasons given.
6. It would appear that there is some common factor at work—namely, the release of antibacterial elements from the leucocytes at the site of damage, influencing the bactericidal power of the blood.

It is of interest to note the results obtained by Colebrook, Eidinow, and Leonard Hill in their work on the effect of radiation on the bactericidal power of the blood in which an increase in the hæmobactericidal power also occurs.

I wish to take this opportunity to express my indebtedness to Dr. L. C. Martin for his constant assistance and suggestions throughout this research and for his help in the compilation of this paper; also to Sick Berth Chief Petty Officer B. Woolcott, my laboratory assistant, who has carried out the practical work and whose skill in the technique involved in these experiments has been of great help and value throughout this research.

# GREAT DILATATION OF THE LEFT AURICLE.

BY C. F. T. EAST, B.M. OXF., M.R.C.P. LOND.,
JUNIOR PHYSICIAN, KING'S COLLEGE HOSPITAL; FORMERLY RADCLIFFE TRAVELLING FELLOW, UNIVERSITY COLLEGE, OXFORD.

THE following is an account of a case which showed a remarkable degree of dilatation of the left auricle. Such a condition was described by Sir Isambard Owen and Dr. Fenton in 1900.[1] Another case was described in THE LANCET in 1923 by Dr. J. G. Emanuel,[2] and a third in 1924 by Dr. Batty Shaw.[3]

### *History.*

The patient was a woman, aged 38 at the time of her death. She was first admitted to King's College Hospital under Dr. H. W. Wiltshire in 1920. She gave a history of rheumatic fever at the age of 16, and after this had had frequent minor attacks of rheumatism. She had also had pneumonia and pleurisy on the left side when she was 21. She had one child 4 years old and had also had three miscarriages. At that time she complained of pain over the base of the right lung. She was thin, cyanosed, and very dyspnœic.

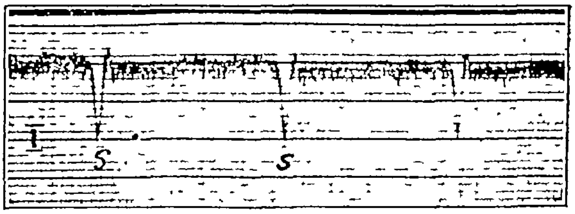
Physical examination showed pulsation of dilated veins at the root of the neck. The chest was rather more prominent on the left side of the sternum than on the right; the apex beat was in the fifth space outside the left mid-clavicular line. Systolic and diastolic thrills were palpable in the mitral area. Dullness extended an inch to the right of the sternum up to the second left rib, and about an inch outside the left mid-clavicular line. A rumbling diastolic murmur was heard near the apex and there was also a systolic murmur conducted outwards. The pulmonary second sound was loud and reduplicated. The apex rate was about 130 a minute and the rhythm showed the complete irregularity of auricular fibrillation. (Fig. 2.) At the right base the breath sounds were poor and percussion note impaired. Pleural frictions were heard here. The Wassermann was negative, the red cell count and hæmoglobin high. Treated with digitalis she improved greatly and compensation became fairly well established.

A diagnosis of mitral stenosis and regurgitation, adherent pericardium, auricular fibrillation, and pleurisy was made. A skiagram taken at this time is reproduced. (Fig. 3.)

In February, 1922, she was again in hospital with acute bronchitis. Again she recovered pretty well. The physical signs on this occasion were as before. Since being in hospital she had attended as an out-patient from time to time, first under Dr. Wiltshire and latterly under my care. Electrocardiograms taken from time to time have shown auricular fibrillation and well-marked preponderating hypertrophy of the right ventricle. She kept fairly well except for occasional attacks of bronchitis. Pain tended to recur at the base of the right lung, especially on exertion. Examined in November, 1925, the same signs were found at the base of the right lung. The cardiac dullness came about 2 inches to the right of the sternum, up to the second left rib, and out to about 2 inches beyond the left mid-clavicular line. Systolic and diastolic thrills and murmurs were present in the mitral area.

In January, 1926, she was admitted under my care with acute bronchitis, very cyanosed, very breathless. The apex rate was about 80, with hardly appreciable irregularity. The beat was very feeble. Dullness came 3 inches to the right of the sternum and extended out to the anterior axillary line on the left. No thrills were felt and the murmurs were very faint. She suddenly collapsed and died soon after admission. Owing to a breakdown only the first lead of an electrocardiogram was obtained. This showed the P wave to be absent and the S wave very marked. The irregularity was very slight. (Fig. 1.)

FIG. 1.



Electrocardiogram Jan. 9th, 1926. Taken just before death. Lead I. only obtained. Auricular fibrillation and what would probably be right side preponderance present. There is slow rate and only slight irregularity; probably due to some heart-block.

### *Autopsy.*

The body was fairly well nourished. There was slight œdema of the ankles. The mediastinal tissues were œdematous. Both pleural sacs were obliterated by adhesions; those on the left were fairly soft, those on the right more dense. On both sides they were dense over the diaphragm. Rather long band-like adhesions lay between the right upper lobe and the pericardial sac. Both lungs showed brown induration and acute bronchitis and a good deal of œdema. The pericardial sac was adherent to the chest wall fairly tightly for about 4 inches to the left and 3 inches to the right of the mid-line. Both lungs were somewhat pushed aside by the heart. The greatest horizontal diameter of the heart as it lay in the chest was about 10 inches. The pericardial sac was thickened. Its cavity was obliterated everywhere by adhesions. These were fairly fine over the left ventricle and could be separated, but over the right ventricle they were very dense. The right border of the heart seen from the front was formed by the left auricle, which projected well to the right from behind the right auricle. At the back the pericardial sac was adherent to the adjacent structures in the posterior mediastinum. In the area in relation to the back of the left auricle it was densely adherent to the medial part of the right leaf of the diaphragm over an area about 3 inches square. The whole heart weighed 31½ oz.

On the whole, the shape of the heart, excluding the left ventricle, was globular. (Figs. 4 and 5.) The right auricle was much dilated and could hold about half a pint. This, and other measurements hereafter given, were made after fixing in formalin, so no doubt some shrinkage had taken place. The inferior vena cava at the point of its junction with the heart had an internal circumference of 3¼ inches. The tricuspid valve was much dilated, and its cusps were a little thickened. The right ventricle was much dilated and hypertrophied. The pulmonary artery had an internal circumference just above the valves of 3½ inches. The valves were large and competent. There were a few patches of atheroma in the main artery and the two branches. The left ventricle was hypertrophied. The wall near its middle was three-quarters of an inch thick, and tightly contracted. The aorta was small; the whole tube from the beginning throughout the arch only admitted a fairly large finger comfortably. Its internal circumference just above the valves was 2¼ inches. The valves were a little thickened but competent. The aorta was rather narrower at the closed ductus arteriosus than anywhere else; there were two areas of thickened intima here ¼ inch in diameter. The mitral valve showed marked stenosis. Its opening took the form of a slightly crescentic slit, just under an inch long. The flaps were fused and the chordæ tendineæ much thickened. The edges of the hole were so hard one could barely force a finger through.

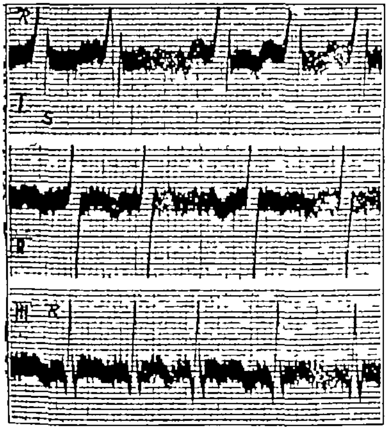
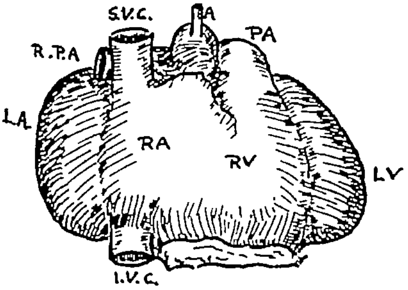
[2] THE LANCET, 1923, i., 591.
[3] THE LANCET, 1924, ii., 493.

FIG. 2.



*Electrocardiogram August 31st, 1920. Showing auricular* fibrillation and right side preponderance. This agreed very well with the relative sizes of the ventricles at autopsy.

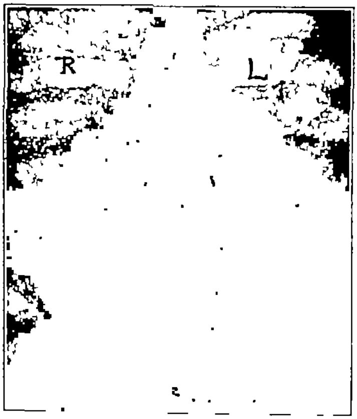
FIG. 4.



Heart. *Anterior view.*

The left auricle was enormously dilated. Its capacity was about one and a half pints. It was full of p.m. clot. The antero-posterior diameter was about the same as the vertical, the lateral was larger. The appendix was practically absorbed into this great chamber. The wall was everywhere very thin, and no muscle could be seen by the naked eye. The left pulmonary veins entered by three openings situated high up in the wall. The lower two were small. On the right side there were two veins, situated high up in the wall, the upper the larger. This huge left auricle passed to the right behind the right auricle which came to lie in front and on a rather higher plane. It completely filled up the arch of the aorta which passed over it and down behind and a little to the left of it. The dense adhesions between it and the right half of the diaphragm have been mentioned. The foramen ovale was quite closed. The bifurcation of the trachea was pressed on by the left auricle from below.

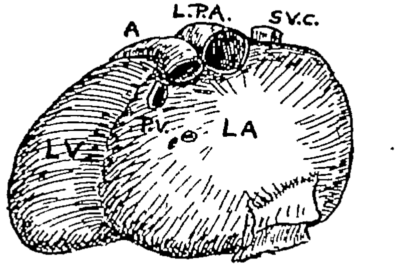
FIG. 3.



Skiagram taken in 1920.

As regards the rest of the organs the liver was of the typical "nutmeg" variety, weighing 8 lb. 10½ oz. There was a little free fluid in the peritoneal cavity. The spleen weighed 0 oz. and was firm and fibrous. The left kidney showed an old infarct in the lower pole and a recent one in the upper. There was no antemortem clot in the heart.

FIG. 5.



Heart. Posterior view.

Microscopical examination of the heart muscle showed the following changes. The left auricle showed a very thin band of muscle mixed with much fibrous tissue. On the pericardial side there were dense layers of fibrous tissue. In the left ventricle there were patches of fibrous tissue with a certain amount of round cell infiltration. These areas were most marked in the zone of fibrous tissue forming the pericardial adhesions. Similar fibrosis was found in the wall the right ventricle, and most of all in the wall of the auricle. Over the right ventricle an active ; process was still at work.

*Comments.*

The condition of the left auricle was not diagnosed in this case during life. In the three other cases referred to, the enlargement of the auricle in a transverse direction was more extensive than in this. It may cause dullness in the right axilla, and it has been tapped here and blood drawn on the suspicion that it was a pleural effusion. The physical signs of the condition, apart from the dullness to the right of the sternum, were not marked. They are characterised by the transmission of the thrill and murmur found at the apex to the right side of the chest. The clearness of these signs must depend upon the closeness of the contact of the left auricle with the chest wall. In this case the right auricle was the part of the heart in contact with the chest wall furthest to the right. The adhesions in the pleural sac in this case seem to have moored the front border of the right lung and so prevented its displacement in this area to any great degree. The left auricle projected well into the right pleural cavity, and formed the right border of the heart as one looked at it, but there was lung between it and the chest wall. The capacity of the auricle was the same as in Dr. Batty Shaw's case, but less than that of Dr. Emanuel, which was 40 oz. Pericardial adhesions have been present in all the cases described, either universally throughout the sac or locally over the left auricle. Mitral stenosis was present in three only; the other three did not show it, though there was evidently regurgitation. One may take it that the pericarditis in all these cases was accompanied by a severe myocarditis. The microscopical findings in my case give some idea of the widespread damage inflicted on the myocardium. Here and there in this case there were signs that the inflammatory process was still active. Perhaps the left auricle suffers exceptionally, and under the high intra-auricular pressure due to the lesion at the mitral valve gradually dilates to this remarkable size.

In mitral stenosis it is usual to find some degree of dilatation of the left auricle together with some attempt at hypertrophy. The state of the chamber at autopsy must depend on the pressure inside it during life, and the condition of the wall after the carditis which affected it along with the mitral valve and pericardium. The left auricle attains a greater degree of dilatation than any other chamber of the heart for three reasons—because it has thin walls, has no safety-valve into the great veins like the right auricle, and is being filled by both ventricles at once when there is mitral reflux.

When one first considers this great transverse enlargement of the left auricle it seems rather remarkable. In the slighter degrees of enlargement it extends backwards under the bifurcation of the trachea. It can readily be seen when the patient is screened in the right oblique position as a rounded shadow projecting backwards from the heart shadow into the retro-cardiac space. A little larger and it fills up the space under the arch of the aorta. Cases have been recorded in which it has pressed on and interfered with the function of the left recurrent laryngeal nerve. It may also press on the œsophagus. Very little enlargement takes place to the left. The arch of the aorta passes over the auricle, and then down, behind it, and a little to the left of it. The left ventricle lies in front and to the left of it, and is in all probability enlarged. It cannot, therefore, expand through the arch of the aorta to the left. The spine lies behind it, so it enlarges to the right and rather forwards. The right auricle then comes to lie in front of it and the right lung, if free, is easily displaced. A very great increase in size occurs of that small piece of the wall of the left auricle that lies between the root of the right lung and the inter-auricular septum a little to the front.

The lesser degrees of enlargement can only be detected by X ray examination in one of the oblique positions, preferably the right anterior oblique. probably quite extensive degrees of dilatation occur not infrequently and are not detected because they give no physical signs. If the shadow projects to the right of the heart, as seen in an antero-posterior view, it may escape recognition as being that of the left auricle unless the direction of its enlargement is borne in mind. It does not give its distinctive physical signs until it is right up against the chest wall. There is no doubt that oblique X ray examination is most helpful in cases of obscure cardiac enlargement.

---

# TWO CASES OF NEOPLASMS OF THE MEDIASTINUM

## WITH UNUSUAL COMPLICATIONS.

BY F. H. YOUNG, M.B. CAMB., M.R.C.P. LOND.,
MEDICAL REGISTRAR, CHARING CROSS HOSPITAL.

CASES of neoplasm of the lungs and mediastinum are probably a great deal more common than are generally supposed, but the unusual nature of the complications in the cases described below make their publication justifiable.

The first is a case of a secondary neoplasm of the mediastinum with an aspergillus infection.

A. L., male, aged 55, came complaining of pain in the knees. Was always healthy until 1917, when the right kidney was removed for hæmaturia and found to contain a hypernephroma. He was a master plumber and had never been concerned with the handling of grain or rope, nor had he kept canaries or other birds.

In December, 1921, he noticed that his knees commenced to creak, associated with gradually increasing pain. In April, 1922, he developed a severe dry cough with small repeated hæmoptyses, and had one or two night sweats. During the summer of 1922 he remained fairly well, but the cough and hæmoptysis persisted. His weight fell from 156 lb. (normal) in April to 136 lb. in December, 1922. In October, 1922, he had an attack of pleurisy in the right side.

When first seen on Oct. 25th, 1922, he had a dull earthy complexion, and teeth and tonsils were septic. Chest: antero-posterior diameter increased. Lungs, right: Movement diminished with slight local flattening at apex; percussion note dull second to sixth dorsal spines behind, impaired over the rest of the lung. Breath sounds broncho-vesicular over the upper half of the lung with increase of voice sounds, but air entry diminished, with a patch of bronchial breathing and bronchophony opposite the spine of the scapula. Coarse râles, increased on coughing, were audible over the upper half of the lung. Left: Note hyperresonant; a few coarse râles and prolonged expiration at the apex. Abdomen: An indefinite resistance was felt in the right kidney region. Sputum was repeatedly negative for tubercle bacilli. Wassermann reaction was negative. Radiography showed a large shadow in the posterior mediastinum; the right apex was opaque. The trachea was displaced to the right. A few days after examination he coughed up a body the size and shape of a small almond, followed by a similar piece a little later.

Microscopic section showed that the first consisted of fibrous tissue with a focus at one point from which the mycelium of a fungus was spreading; the second consisted entirely of fungus, the only normal tissue being a layer of striated muscle perforated by the fungus. A culture of the material showed a considerable growth of aspergillus fumigatus. Injection of this into a rabbit caused death from aspergillus pyæmia. Agglutination and complement-fixation tests on the patient for the aspergillus were both negative.

In November, 1922, he was admitted to St. Bartholomew's Hospital under Prof. F. R. Fraser, who has kindly allowed me to use his notes. The temperature and pulse were usually slightly raised. He was treated with large doses of potassium iodide without effect and later with X rays under which his weight increased to 148 lb. and he was generally improved.

He was discharged in January, 1923, and remained fairly well till March when he relapsed, was readmitted and died with signs and symptoms of acute bronchitis.

At post mortem the left pleura was not adherent, the left lung showed patchy broncho-pneumonia, especially at the base, and much emphysema. The right pleura was densely adherent and the lung showed broncho-pneumonia. The mediastinum was occupied by a mass of mottled greyish growth with considerable necrosis from which protruded into the left main bronchus two rounded firm masses. The left kidney was hypertrophied; the right was replaced by a mass of growth the size and shape of the kidney. No other secondary growth discovered. The nasal sinuses were unfortunately not examined. Section showed: Lungs, acute broncho-pneumonia; mediastinal mass and mass in right kidney showed the structure of a papillary carcinoma of the kidney; suprarenal, no evidence of growth. In none of these organs was there any trace of aspergillus fungus. By a process of exclusion it is nearly certain that the aspergillus coughed up must have come from the nasal sinus

I am greatly indebted to Dr. L. P. Garrod for the extensive pathological work.

A considerable number of cases of combined aspergillus infection and mediastinal neoplasm have been reported, but I cannot find records of any which have been so completely worked out from the pathological point of view. The disease is very rare in England, the majority of the cases recorded having occurred among the bird fanciers in Paris. The case is also of interest: (1) On account of the length of time, over four years, between the occurrence of the primary and secondary growth, as in this type the secondary growth nearly always occurs within three years of the primary. (2) On account of the markedly beneficial temporary result of X ray therapy; the patient gained 12 lb. in weight and his symptoms were much ameliorated.

The second case is one of a neoplasm of the mediastinum, possibly primary, but probably secondary, associated with tuberculosis of the lung

J. P., aged 42, labourer, complained of pain in the left side. Malaria 1919, dysentery 1908, otherwise healthy. Since 1920 had abdominal pain after food with flatulence and vomiting, but no hæmatemesis. In October, 1923, he commenced to cough and have acute pain in the left chest. The cough was at first *dry*, but *later he had a profuse* greenish expectoration, sometimes blood-stained. He commenced to lose weight, and his appetite began to fail. On examination on Oct. 15th, 1923, he looked ill, and had obviously lost weight; fingers slightly clubbed, teeth septic. He was dyspnœic and slightly hoarse. Lungs, right: Slight hyperresonance, otherwise normal; left, movement much diminished, especially at the base. Air entry practically absent over the middle third, and diminished over the remainder of the lung. Dull to percussion from the second rib in front, and from the spine of the scapula behind. Breath sounds faintly bronchial, a few medium râles scattered throughout the lung. At the extreme base the note was less impaired and the breath sounds were broncho-vesicular. Abdomen: Diffuse tenderness in the upper part. Larynx, arytenoids, and cords slightly inflamed, no ulceration, no paralysis. Radiography showed that the left diaphragm moved *slightly less than the right*; on the left side the middle third of the lung was obscured by a dense, but not quite uniform shadow, which also occupied the posterior mediastinum. The edges were not discrete, and there was haziness of the remainder of the lung. On the right side there was exaggeration of the normal striation. Sputum at first negative, afterwards repeatedly positive for tubercle bacillus. Wassermann reaction negative. Blood count showed a slight secondary anæmia.

He went rapidly downhill and died at the beginning of December with signs and symptoms of acute bronchitis.

A post-mortem was performed by Dr. W. A. Young, pathologist to the Royal Chest Hospital, to whom I am indebted for the following extracts from his report.

The right pleural cavity was free from adhesions. Left lung was completely adherent to chest wall. When left lung was being stripped the pleura was ruptured and about two pints of thin greenish yellow pus were evacuated from the lung, which, on section, was found to be a series of ragged, communicating cavities with thick fibrous walls covered with necrotic tissue. The upper lobe was invaded by a dense yellowish growth spreading from the mediastinum. Some separate nodules were found the size of small chestnuts in the upper lobe and some smaller subpleural nodules on the posterior surface of the lower lobe and on the ribs and vertebræ in association with them.

In the necrotic sides of some of the cavities and in the subpleural region a few areas suggesting *tubercle formation* were noted; but these were indefinite in the presence of so much necrosis and sepsis. The glands in the left hilum were completely infiltrated with growth and continuous with the mediastinal mass. The left bronchus was completely obliterated and occluded. The right bronchus and trachea showed ulceration, fibrinous exudation, and general congestion of their mucosæ. The right lung showed old scarring of the apex, terminal œdema, and no signs of active phthisis. The mediastinal mass appeared to be an agglomeration of malignantly infiltrating glands, surrounding large vessels, but not infiltrating them, the trachea, or the œsophagus. In the bifurcation, in the region of the left bronchus, and to the left of the trachea the greatest amount of growth occurred.

*No* enlarged glands found in the neck.

*Liver* extended two fingers breadth below costal margin; on section it showed passive congestion and cloudy swelling. A small nodule, the size of a small pea, was removed for section.

*Stomach.*—Much *dilated. At the pyloric end were* a few adhesions to the gall-bladder and to local peritoneal surfaces. At this place the wall felt thickened, and on opening the stomach an ulcer was found about the size of a five-shilling piece, immediately adjacent to the pylorus on its antero-superior *aspect. The margin of the ulcer* and the base were moderately thickened.

*Section.*—Examination of sections of the main tumour mass and various deposits showed the typical structure of a pavement-celled type of endothelioma.

In the *left lung*, along the growing edge of the tumour, small *processes of malignant* cells could be seen growing into the terminal bronchioles and alveoli, in some cases engulfing and surrounding catarrhal cells. The alveolar walls, which separate these processes, are apparently being slowly absorbed, as they are traced deeper into the tumour. In some sections the tumour is seen to be growing directly into *fibro-caseous tuberculous areas*, with typical tubercle systems with giant cells and the usual granulation tissue and surrounding broncho-pneumonic areas. In these tubercle systems Koch's bacilli were demonstrated adjacent to processes of malignant cells.

In the *thoracic glands everything from* early typical deposits to older degenerated, and in some cases fibrosed, deposits were found. In the liver was a small deposit of the same structure as the mediastinal mass, in association with early miliary tubercle in Glisson's capsule. One small tubercle system was found immediately adjacent to the *deposit* of growth.

Sections of the ulcer at the pyloric extremity of the stomach show chronic inflammatory fibrosis of the base and margin, fibrous tissue replacing the deep muscle layers. The epithelium at the edge of the ulcer shows simple degenerative changes alternating with *inflammatory hyperplasia* in the form of epithelial overgrowth and the formation of some solid columns of cells, which are suggestive of early malignancy. The granulation tissue was sparsely cellular in character, with a few areas of round-celled infiltration and the characteristics of tuberculous granulation tissue with increase *of endothelioid cells*, &c., but no tubercle systems were found. In the fibrous layers in the path of capillaries and lymphatics areas of marked endothelial proliferation were found. In several instances these areas contained cells which were sufficiently metaplastic strongly to suggest early malignancy.

From the pathological standpoint there are two points of marked interest in the case. (1) The association of an intrathoracic tumour *growing into the lung* with tubercle and the association of secondary deposits and miliary tubercle *of the liver*. The former has been reported on several occasions previously, but I can find no record of the previous demonstration of the growth actually invading the tuberculous tissue, and the occurrence of the secondary deposits of the growth associated with *miliary* tubercle of the liver also appears to be unique. (2) The possibility of a gastric origin for the intrathoracic tumour. This is a suggestion only.

Considering the two cases together they form an interesting commentary *on the fallacy* that may arise if too much stress is laid on the pathological findings. Both cases from the clinical point of view were fairly typical of intrathoracic neoplasms and the radiographic findings were greatly in favour of that, and the condition was confidently *diagnosed* prior to the reception of sputum reports.

---

MEMORIAL TO DAME LOUISA ALDRICH-BLAKE.—A committee upon which the London School of Medicine for Women, the Elizabeth Garrett Anderson Hospital, and the Royal Free Hospital are represented, has decided upon the form of memorial to this distinguished surgeon. A travelling scholarship is to be endowed, open to women graduates from all the medical schools in the United Kingdom, and copies of Dame Louisa Aldrich-Blake's portrait by Sir William Orpen are to be hung in the Royal Free Hospital and the Elizabeth Garrett Anderson Hospital, at both of which she was consulting surgeon. Possibly, also, a bust may be erected in some public place

# Medical Societies.

## ROYAL SOCIETY OF MEDICINE.

### SECTION OF SURGERY: SUBSECTION OF PROCTOLOGY.

A meeting of this Subsection was held on June 9th, the chair being occupied by Mr. G. Grey Turner, the President, when a discussion on the

### *Value of the Closed Methods in Resection of the Colon*

was opened by Prof. John Fraser (Edinburgh). The operation of closed anastomosis of the colon was, he said, of interest, apart from the technique of the surgery, in that it represented a striving for an ideal. Since Halstead's paper, 32 methods had been described for effecting this anastomosis, a fact which showed that the ideal operation had not yet been reached. In dealing with statistics he did not include closed methods, and, excluding the surgery of the war, the mortality of anastomosis of the small intestine was 4·8 per cent., and in the anastomosis of small to large intestine it was 7·5 per cent. to 8 per cent. In anastomosis of the large intestine, when carried out without any additional procedure, such as Mikulicz's, or a combination of cæcostomy with anastomosis, the mortality was about 25 per cent. When, however, the operation was done in two stages, or when cæcostomy was added, the mortality fell to 12 per cent. There was, he declared, a large element of risk in doing primary suture of the large intestine, and it was of interest to inquire why there should be such a striking divergence between the mortality figures of small intestine anastomosis and those applying to the large intestine. It depended on the bowel wall. Beneath the endothelial layer of the peritoneum was the tunica propria, in which ran some lymphatics and fine blood-vessels, and this tunica possessed great defensive power against infection. If in an intussusception a small rent had passed unnoticed it might become the channel of infection to the gut. In the large intestine the tunica propria was often replaced by fat, and the stouter the individual the greater was this amount of fat. That entered largely into the question of the danger of suturing the large intestine. In the latter, too, the blood-vessels were comparatively scanty, and in the anterior mesenteric area the blood was not plentiful. In subjects of chronic obstruction the area above the seat of obstruction was more toxic than in a condition of health, and this could not be left out of account in assessing the risks. Moreover, the peristalsis in the large intestine was of a very powerful type, and this meant that the line of suture was liable to considerable mechanical strain.

### *The Edinburgh Technique.*

Prof. Fraser's first work in closed anastomosis was done on dogs, whose large intestine was difficult to deal with, it was very thick and resistant, its blood-supply was rather deficient, and, the dog being a meat eater, the intestinal flora was much the same as in man. A V-shaped incision was made in the mesentery, and when the blood-supply had been ligatured, strong clamps were put on and that portion was cut away. Then two needles were threaded with 00 catgut, and the ligature was passed through the eye of the guillotine on each segment of the bowel to remain. The ligature must run as close as possible to the crushing flap, which was important, as it made all the difference between success and failure. The clamps were removed, the ligatures tied, and the guillotines fastened to the closed end of each bowel. Probably the best type of stitch to use was Halstead's buttressing interrupted suture, and that was probably sufficient, but, in order to be on the side of safety, he usually added a thin continuous suture over the surface. Then the ligature was cut and released, the guillotines were slipped out, and there was no fear of infection. When the suture was completed care was taken to finish it carefully over the point at which the guillotine had been removed. It was essential to invaginate with the finger the line of suture so as to open it freely and completely. Prof. Fraser showed a number of slides of the operated areas at various intervals afterwards. Even in 36 hours the serous peritoneum had completed its junction over the periphery, and in 76 days it was almost impossible to see the outline of the junction; 54 animal experiments were done, and no deaths occurred. Before advising the routine use of this operation, he thought it should be more widely employed by those constantly engaged in abdominal work, as it was still comparatively untried. In the human subject he had done it in 14 cases, with one death, but others in Edinburgh had employed it without a death so far. The operation could be done very rapidly—in from 10 to 15 minutes—and in situations where any more specialised method would be very difficult.

### *The Dublin Technique.*

Mr. Seton S. Pringle (Dublin) described the closed method he employed, which varied in certain particulars from that of Prof. Fraser. As he progressed he had seen no reason to alter his technique. He was satisfied that it was a quick operation and that the risk of infection was much less than with the ordinary methods. He showed the clamps he used in the operation for crushing the bowel, the bowel being divided through the crushed portion and carbolic acid applied to the portion projecting beyond the forceps. The mesentery was united up to a short distance from the bowel, and when the ligature was tied there was a gutter of folded intestine. The intestine was then turned over and similarly treated on its other aspect, so that there was only a small area where the serous coats of the intestine were not in contact. The forceps were removed, and the small gap remaining was closed by a stitch. He had used the method in 14 cases, with two deaths, the first in a man in very poor general condition, with advanced carcinoma of the descending colon, adherent to the lateral abdominal wall and with a pericolic abscess. The other case who died was of great interest. It was that of a man, aged 68, who had a ring cancer of the pelvic colon. At first he made excellent progress; the wound healed by first intention and the bowels acted regularly. But on the tenth day he had a temperature of 102° F., and two days later it was evident that thrombosis of the left femoral vein had occurred. A blood culture taken on two occasions produced a non-identified member of the coli group. Death was from septicæmia on the thirty-second day. Apart from these two cases the results of the operation had been very pleasing to him, for the patients made a straightforward recovery and there were no signs of intra-abdominal infection, except that one developed a mild infection of the abdominal wall. In no case was there serious obstruction due to the formation of a shelf. By this method the mucous membrane was not seen or exposed, and one could place the sutures closer to the line of section of the intestine than if the gut had been enclosed by an encircling ligature. Twenty-three days after the operation X rays after a barium meal only just enabled the line of resection to be seen. Even when a shelf did form, Halstead had shown that if there was neither trauma nor sepsis the ridge rapidly unfolded. Schumacher recently told the speaker that he still did closed colectomy as a routine.

### *President's Remarks.*

Mr. Grey Turner said it was very likely there was much in the claims for speed and simplicity in regard to the closed operation, and it might result in an increase of the operability rate, but he questioned whether the case for a diminished mortality because of a lessened risk of sepsis had been made out. The cause of mortality after resection and anastomosis of the large bowel at the present day was not so much sepsis as some defect in the blood-supply of the part. In the immediate past much of the mortality was due to attempts made by surgeons to carry out resection and anastomosis of the bowel in the presence of a sodden and septic condition. Another cause was the selection of the wrong time for carrying the operation out. The great advancement in the matter of resection had been the preliminary treatment, which usually meant preliminary cæcostomy. In the cases he most regretted the trouble had been due to some defect in the blood-supply, which had been noticed. If he had any doubt on that point now he removed the clamps before commencing to assure himself, as far as he could by inspection, that there was an adequate blood-supply all round. If surgeons were wedded to the closed method, however, that could not be done. With great care as to details in the ordinary methods, he doubted whether sepsis was likely to be a common cause of failure. He agreed that the closed method enabled the anastomosis to be carried out with greater speed, though he doubted whether the saving in that respect would prove to be of any great importance. He would like to see either Prof. Fraser or Mr. Pringle carry out their method of colectomy in a big fat person, scarcely any part of whose peritoneum was visible. He considered catgut the ideal suturing material.

### *Discussion.*

Mr. P. Lockhart-Mummery said he had practised the closed method, but not that described by either of the opening speakers. He still believed that, save in exceptional circumstances, the open method was the better. The exceptions were the cases in which the growth was in a very inaccessible position, when, if the open method were chosen, the manipulations would have to be done in the abdominal cavity. With regard to the objections to the closed method, he did not include among these the formation of a spur, as that seldom occurred in actual practice. And the bringing together of mucous membrane was not important, as it closed in an extraordinary way. In his view the chief objection was that a large piece of bowel was crushed, and he had not satisfied himself that the juice which appeared as a result of the crushing was aseptic. A second objection was that the surgeon relied for hæmostasis on crushed vessels. He thought serious trouble from hæmorrhage was to be expected, as by this method there was no control of bleeding except by the crushing. The operation of crushing for piles was discarded because of secondary hæmorrhage. He preferred the method by which the bowel was simply stitched together. The factor which made for safety in the open operation was the preliminary or temporary cæcostomy, done at the same time. He had done practically all his cases by the open method, with temporary cæcostomy, and out of his last 20 cases so dealt with he had lost only one. The present smaller death-rate was largely due, he thought, to surgeons recognising the necessity of having a safety-valve above the line of union. He used the through-and-through stitch, locked every five stitches, then started the peritoneal stitch at the junction of gut and mesentery, and brought it straight down the gap on the inner side, leaving the gut at the outer side open, as he thought that one cause of trouble was that there might be hæmorrhage between the layers of the mesentery and that damaged the blood-supply. He admitted the advantage of the closed method when the open operation was not available.

Mr. Aslett Baldwin said the path of safety lay in doing a preliminary cæcostomy or colostomy, which he carried out through the right rectus. He had always done the open method of suture. He agreed with the President that the great risk was from sloughing of the bowel. It was important to make sure the bowel had got its proper blood-supply before suturing it.

Dr. F. J. McCann said he had operated on the colon a number of times for the removal of growths, &c., and he used the open method. He agreed with what the President said as to the manner of application of the sutures. He used one continuous suture, care being taken that the tissues had not been devascularised. He appreciated the great value of preliminary cæcostomy, which he believed to be of enormous influence in reducing mortality.

Mr. E. W. Sheaf (Guildford) said he had carried out Prof. Fraser's method in four cases. One case, a very severe one, died some days later of pneumonia, and at the post-mortem one could see no evidence of trouble in the transverse colon. He was much impressed with the value of the operation. By it one was better able to avoid contamination than by the open method.

Mr. H. O. Butler remarked that he had used Prof. Fraser's method in two cases, one of which was a failure probably due to the speaker's defective technique. He brought a specimen in which there was a very definite shelf, which formed after the operation, and only a moderate-sized probe would go through the opening.

Mr. Cecil Rowntree expressed his intention of using the closed method in future. Prof. Fraser's seemed to him the more *safe* of the two, and Mr. Pringle's the quicker. Animal experiments had played an important rôle in establishing this operation, and it was a pity there were not more opportunities taken to do experimentation in this country. Crushing he regarded as an efficient hæmostatic.

Mr. Ivor Back spoke of a case in which he carried out Prof. Fraser's method for resection of a carcinoma from the descending colon, without cæcostomy. The patient, a woman, passed a normal motion on the third day, but on the ninth day the temperature began to rise and she complained of pain. The temperature lasted two days, and as the abdomen became tumid he concluded there was leakage. He reopened the last inch of the incision and came upon a large abscess, which occupied the pelvis and contained thin fluid, which was obviously *B. coli*-infected. He inserted a tube and she recovered, the temperature coming down to normal. By testing with methylene-blue he found the urinary apparatus was involved, and it seemed clear that the abscess had infected a small part of the base of the bladder and set up a communication. For some days she passed urine both in the ordinary way and through the wound, then the wound closed and she made a complete recovery. He had been much impressed by the greatly increased facility with which the closed operation could be done in comparison with the open, and one was not impeded by the fear of having a contaminated field at the operation. He *also* agreed that crushing sufficed to produce hæmostasis.

Mr. W. B. Gabriel referred to a case of carcinoma of the hepatic flexure without obstruction, in which anastomosis was done by Mr. Pringle's method. Cæcostomy was not done, and the convalescence was uneventful, the patient leaving the hospital three weeks after the operation. He suggested that in the absence of obstruction cæcostomy could be dispensed with.

### *Reply.*

Mr. Pringle said he could not agree that sepsis was a negligible risk in the case of the open method of operation; there must be some soiling of hands and materials, and this was avoided by doing the closed operation. The possibility of the formation of a shelf must be borne in mind when operating and especially when suturing. Whenever he had his big crushing clamps with him he did the operation as a routine. He had not seen any trouble with metastasis.

Prof. Fraser said he had not abandoned the open method in his practice, but he considered that the closed form of operation had a great field. In the matter of speed of operation the closed method was infinitely to be preferred, as he could do it in five minutes. As to the President's remark that he would like to see the open method attempted on a fat colon, that was just the kind on which its greater safety was demonstrable. With regard to the possibility of shelf formation, he recognised that, but one layer of sutures would probably be found sufficient. In the human subject he had never seen bleeding after the operation. A shelf would be avoided by omitting cæcostomy.

## SECTION OF OTOLOGY.

THE summer meeting of this Section was held on June 4th and 5th, Mr. G. J. JENKINS, the President, occupying the chair.

The PRESIDENT read a paper, supplemented by a cinematograph demonstration, on

### *Cystic Serous Meningitis.*

He said that Bing, Bárány, and others had described cases in which there was an accumulation of subarachnoid fluid in relation to the anterior aspect of the cerebellum. In the two cases now put forward the symptoms and signs spoken of by Bárány could not be demonstrated, but the cases seemed to indicate that some such pathological conditions as those authors described did occur. Both patients had a history of chronic mastoiditis, an inflammatory process in the mastoid region, and of extensive operative treatment. The labyrinth was intact in both patients. Hysteria was very marked in both, but beneath this were indications of an organic lesion. The general debility, hysteria, giddiness, tinnitus, and headache came on gradually, and were long-standing symptoms before Mr. Jenkins saw the patients. They were in a desperate condition, and at first it seemed that nothing could be done for them. He then thought there might be a septic condition in the posterior fossa, behind the chronically inflamed mastoid region. Accordingly he incised the dura between the lateral sinuses and the labyrinth, and he found a considerable depth of subarachnoid space at a part where, usually, the cerebellum was in intimate contact with the dura, and there was a free flow of cerebro-spinal fluid in making the opening into that space. Both patients experienced relief of their symptoms within 24 hours of the operation. His object in reading the paper was to initiate a discussion on the possibility of accumulations occurring in front of the cerebellum.

Mr. LIONEL COLLEDGE spoke of a comparable case which he had seen in a girl aged 19. She had had a radical mastoid operation, but the cavity was soundly healed when he saw her. She also was hysterical, and had in fact been condemned as a hysterical subject. She complained of the same symptoms as did Mr. Jenkins's patients. The labyrinth seemed intact. She had a pronounced pointing error. He trephined through the occipital bone, the cerebellum bulged into the wound, and on displacing it backwards with the spatula there was a gush of cerebro-spinal fluid. The brain at once started pulsating, and the patient had immediate relief of her symptoms.

Mr. SYDNEY SCOTT said this condition might occur more frequently than was supposed, one reason cases might be missed being that the surgeon deliberately avoided puncturing septic cases. He mentioned the case of a man who had middle-ear suppuration for four and a half weeks, with a profuse discharge from the ear. On opening the mastoid Mr. Scott found the dura mater lying bare in the mastoid cavity, and in an almost sloughing condition. On passing in his finger to feel the boundaries of the area exposed between the labyrinth and the sigmoid sinus, his finger passed through into the cerebellar fossa, and there was a rapid flow of clear cerebro-spinal fluid. He thought there must have been an excessive effusion of cerebro-spinal fluid there, just as occurred in the knee-joint or in the pleural sac.

Dr. J. G. FORBES spoke of similar accumulations of cerebro-spinal fluid as a result of post-nasal or cerebro-spinal meningitis, and described a case of the kind.

Mr. F. W. WATKYN-THOMAS described a similar case, this patient also having had a mastoid operation. She had severe headache and giddiness, with a tendency to fall to the operated side, and a past-pointing error on the same side, with some nystagmus. The speaker thought it might be some pre-cerebellar condition, and Mr. Wyllie was about to operate when there occurred a sudden gush of clear fluid from the old operation cavity and a complete relief of the symptoms followed.

### *An Unrecorded Aqueduct in the Bird's Labyrinth.*

Dr. ALBERT A. GRAY (Glasgow) read a paper on an Aqueduct in the Bird's Labyrinth not previously recorded, and its evolutionary significance. He showed that this was a very short tube, of very fine calibre. It was present in the labyrinth of most species of birds. It was a fine canal, which ran through surrounding bone from the ampulla of the posterior canal to the recessus perilymphaticus. It was less frequently found in the more specialised birds, such as the singing varieties, and crows.

Dr. H. HARTRIDGE (Cambridge) read a paper on the

### *Fundamental Experiments on which the Resonance Theory is Based.*

He said the evidence on which the resonance theory of hearing was based was of a very diverse nature. He described, by means of the epidiascope, the ingenious apparatus by which he conducted his investigations on the subject. The question resolved itself into this: Does the ear possess the property of persistence of sound? It must if it contained resonators. And if it did, how could one hear an interruption in a musical tone? He argued that the ear certainly does show persistence of tone, and that the physical evidence he was able to submit fitted in with the physiological. The phenomena which took place in the ear could not occur unless there were in it suspensory discs of some kind, acting as resonators. He purposely did not enter into the question of where in the ear these were situated. He described and commented on the models of Ewald and of Wilkinson, and the deductions those authorities made from them, remarking that models did not behave exactly as did what they were made to represent, and the mere fact that Ewald's model was on a different scale to that of Wilkinson, and that different materials were employed, was sufficient to account for the divergent conclusions arrived at.

The subject was discussed in considerable detail by the PRESIDENT, Mr. SCOTT, Mr. G. WILKINSON, and Dr. GRAY, and Dr. HARTRIDGE replied.

A number of interesting cases were shown and discussed.

During the meeting Messrs. Allen and Hanburys, Messrs. Down Bros., Messrs. Meyer and Phelps, and the British Colloids Co. exhibited their products in the Barnes Hall.

## NORTH-WESTERN TUBERCULOSIS SOCIETY.

### *Tuberculosis of Joints.*

A MEETING of this Society was held at the Medical School of the University, Manchester, on June 4th, Dr. A. ADAMS presiding. Sir ROBERT JONES gave an address on this subject.

*Tuberculous Joints in Children.*—Sir Robert Jones said that tuberculosis of joints was chiefly a disease of children. Eighty per cent. of cases occurred between the ages of 2 and 14 years. When the disease occurred before that age it ran a grave course. The onset of disease corresponded to the activity of epiphyseal growth when the epiphyseal blood-supply was most abundant. It should be clearly emphasised that the disease was not hereditary. Heredity—in its Mendelian sense—dealt with unit characters transmitted through successive generations in accordance with definite laws. It was unthinkable in terms of heredity that a bacillus—like the tubercle bacillus—could be transferred in this sense, as it would have to be carried in sperm or ovum as a foreign body. If conveyed through the placenta the case would be taken from the hereditary class and placed in the congenital. Congenital transmission dealt with any infection which occurred to the fœtus from the moment of fœtalisation to birth. The cases of congenital tuberculosis were sufficiently rare to be of no practical importance. A tendency to the disease by way of increased susceptibility might be transmitted. Anything which diminished resistance predisposed to infection. Embryonic tissue had been proved by experiment to be very resistant to tuberculous attack. Tissues which could resist small doses of tubercle would succumb to large ones. The only absolute proof of the presence of tubercle in a joint consisted in the identification of the bacillus, inoculation of a guinea-pig, or the histological evidence. Specific tests, such as the von Pirquet, were of more value in their negative than in their positive reaction. Blood tests in spite of the investigations in regard to tuberculous antigens were of no practical value. Joints were attacked mainly by the bovine bacillus. Infection occurred chiefly through inhalation of infected dust finding its way to the blood stream via adenoid tissue, tonsils, and bronchial glands, or through the small intestine. Clinical evidence and experiments on tuberculous animals clearly established the exciting influence of trauma.

Sir Robert Jones discussed at length the significance of symptoms, describing the early and later deformities. The most significant symptom of activity was rigidity, with limitation of movement in all directions. If movement were found to be free in any one or more directions that was evidence that recovery had taken place. Paralysis occurred in association with only slight angulation and might be absent in very pronounced angulation It might recover with increasing angulation The paralysis was due to pressure from pachymeningitis, from epidural exudates, or from a collection of fluid debris. Recovery generally occurred in six months, although there might still be recovery from paralysis after many years. Operation was, therefore, rarely needed. In caries of the spine the bodies were affected, and laminectomy would dangerously weaken the spine In discussing treatment, emphasis was laid on the fact that the disease was a local manifestation of a general infection The aim of treatment was to improve resistance, protect the joints, and prevent deformity.

*Tuberculous Joints in Adults*—Tubercle in the adult, Sir Robert Jones said, was almost a different disease from tuberculosis in the child. It meant a prolonged convalescence—often years in duration—and resulted in a firm fibrous or bony ankylosis. The disease in adults was more prone to general dissemination, and in consequence the speaker recommended early operation to shorten the duration of disease. The aim of operation was to ankylose the joints. The duration of disease in this way was shortened to months rather than extended to years. In children operation was very rarely justifiable, and the days of excisions and erasions must be considered as passed. Patients were to be met with to this day who had flail and shortened limbs as the results of meddlesome surgery.

*Abscesses*—As to abscesses, attention was drawn to the fact that they were generally absorbed if left alone, and often became isolated and cut off from the original focus. An intra-articular abscess in this way became extra-articular. Aspiration did not hasten recovery, and this procedure was only needed if the abscess became very large and threatened to burst, or if invasion of micro-organisms suggestive of sepsis was suspected. If the abscess were benign, but threatened to burst under reddened skin, a very minute incision should be made at the thinnest part. Infection was more likely to take place if the incision were made through healthy tissues. Scraping of an abscess cavity and the use of drainage-tubes was emphatically condemned.

*Conservative treatment* should include fresh air and sunshine and complete rest and fixation of the joint. Deformities were the result of neglect or ignorance. They should be anticipated. Splints should be of a simple type. The hip should be kept extended and slightly abducted, the knee extended, the ankle at right angles, the shoulder abducted, the wrist dorsiflexed, and the elbow at right angles. Hospitals for children, excepting for acute cases, should not be tolerated in crowded cities. Heliotherapy had proved a most useful adjunct to outdoor life, but great care should be taken that in joint lesions no relaxation in regard to mechanical fixation should be allowed. Artificial light was advocated when the sun was not available. The signs of recovery were discussed and the methods of gradual diminution of mechanical fixation. A joint which increased its range of movement had recovered. If the range decreased, restraint was necessary. If an ankylosed joint altered in its angle during use it was essential to prevent movement.

The necessity of prolonged supervision of tuberculosis in a joint was emphasised. Ankylosis was fibrous, and fibrous tissue contracted for years, long after active tuberculous disease was ended. An angular flexion of spine could increase owing to the influence of gravity, and should be supported long after the disappearance of disease. This all meant continuity of treatment and efficient, skilled after-care. In conclusion, Sir Robert Jones demonstrated the use of splints and appliances.

---

## BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

At a meeting of this Society held on June 3rd, Dr. E. Rivaz Hunt, the President, being in the chair, Mr. M. Fitzmaurice-Kelly read a paper on the

### *Cure of Hernia.*

In reviewing the progress made in the last quarter of a century, Mr. Fitzmaurice-Kelly remarked that the title of his paper represented an ideal to which we were now substantially attaining. One of the chief factors in the causation of recurrences, wound sepsis, was now practically abolished. The saccular theory of Hamilton Russell was discussed. Mr. Fitzmaurice-Kelly believed that though it accounted for many cases, it was not as universally true as its advocates claimed, and that, from the practical point of view, while there were many cases in which the sac was the cause of the hernia, and its removal was sufficient to effect a cure, there were many in which there was damage, either primary or secondary, to the abdominal walls, which called for some measures of plastic repair. Discussing the methods advocated, Mr. Fitzmaurice-Kelly thought that any method which sought to displace muscles by sutures was foredoomed to failure, and that such stitches did more harm than good. For a time, the method of filigree implantation had many advocates, and in many cases of ventral and umbilical hernia it had given good results; in large inguinal hernia the results were less certain, and any recurrence was very difficult to deal with. Further, wound infection was not uncommon and was fatal to success. Transplantation of patches of fibrous tissue was introduced to deal with cases, such as direct inguinal and ventral hernias, in which there was a defect of the abdominal wall to fill. The immediate results were good, but many recurrences were reported owing, it was said, to the absorption of the transplant. But this conclusion was traversed by Gallie, of Toronto, who showed by careful experiments that the union of the transplant to the edge of the defect was the weak spot. To meet this he devised the method of using his fibrous tissue transplants in strips, in the form of living sutures, thereby fixing them immovably to the margins of the defect to be filled. The application of this method to many varieties of hernia, especially to recurrences, and cases not amenable to other methods of operation, was described, and Mr. Fitzmaurice-Kelly claimed that since its introduction a large number of patients previously regarded as hopeless could now be cured, and that in all cases in which the removal of the sac was insufficient it was the method of choice. Particularly was this the case in old patients with direct hernias, and in this connexion the use of spinal analgesia and the consequent immunity from lung complications was important.

### *Discussion.*

The PRESIDENT asked whether it was necessary for the patient to lie up for a longer period after the living suture operation than after the more usual methods.—Mr. GEOFFREY BATE said he had originally been rather sceptical, but was now a convert to the method. He asked if any trouble was experienced with the wound in the thigh, and thought that many patients might object to such a large incision apart from the hernia wound.—Mr. H. N. FLETCHER mentioned Southey's method of silk implantation, and said that in umbilical hernia he had had very good results with Mayo's method of overlapping the aponeurosis. While the living suture method was probably the best for large ventral hernias, many of the slighter cases could be cured by layer to layer suture. He agreed as to the importance of spinal analgesia in preventing post-operative lung complications.

Mr. Fitzmaurice-Kelly, in reply, said that Gallie's researches showed that vascularisation of the graft was complete in three weeks, and there was no reason in these cases for a prolonged convalescence. He had had no symptoms referable to the thigh incision in any of his cases—in most, it was easy to suture the gap in the fascia, but when three or more lengths had been taken, the gap had been left open without any disability resulting. With regard to Mayo's operation for umbilical hernia, and many other of the older methods, it was certain that good results had been achieved. But all along the line the difference between the best surgery and the second best was represented by a small but constant percentage, and any method which gave a prospect of definite improvement in results should be adopted. Gallie's results in over 100 cases (mostly relapsed or rejected as unsuitable by others) so far showed no relapses, and this was a great advance on the results of any other method in similar cases. While not denying that the filigree method and Southey's method had rendered service, he thought the method of living sutures was sounder in principle and better in practice, and should supersede them.

---

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on June 2nd, Mr. ALEXANDER MILES, Vice-President, being in the chair.

Dr. W. T. RITCHIE gave a communication on

*Paroxysmal Tachycardia,*

based on a study of 14 personal cases and of cases recorded in the recent literature on the subject. Of the personal cases, one was auricular, one nodal, eight ventricular, and four of undetermined origin. The general symptomatology and clinical signs having been described, details were given of illustrative cases. The longest paroxysm was one of ventricular origin in a man aged 29, who had been subject to paroxysms for 14 years; a final paroxysm at a rate of 237–240 was terminated by death on the ninth day. The longest paroxysm on record was one of 15 months' duration in a man aged 22. The frequency of paroxysms was most inconstant; they might occur at intervals of seconds, minutes, hours, days, or years. Paroxysms usually ended spontaneously. No method was known whereby paroxysms of nodal or ventricular origin might be arrested. Attempts to arrest auricular paroxysmal tachycardia met with more success, and such measures as deep breathing, holding the breath, drinking of cold water, straining while the glottis is closed, or firm compression of the abdomen succeeded in some cases. All these measures, if successful, probably acted as does ocular compression by reflex vagal stimulation. Dr. Ritchie held that direct compression of the right or left vagus in the neck was the most effective means of arresting auricular paroxysmal tachycardia. In diagnosis, paroxysmal auricular fibrillation could readily be excluded. It was not so easy to exclude auricular flutter. If vagal compression caused transient slowing of the ventricles, and if this effect passed off rapidly after the vagal compression had been relaxed, it was clear that the case was one of auricular flutter. If vagal compression caused the ventricular rate to fall suddenly to normal—e.g., from 160–180 to 80—and the latter rate was maintained after withdrawal of pressure from the vagus, the attack was undoubtedly one of auricular paroxysmal tachycardia. Electrocardiographic examination was, however, the most reliable means of establishing the diagnosis. The prognosis depended on the degree of integrity of the cardiac muscle and valves rather than on the rate and duration of the tachycardia. The risk attending the administration of digitalis and strophanthus appeared to be greatest in paroxysmal tachycardia of ventricular origin. Quinine and quinidine were probably of little therapeutic value in arresting paroxysms.

In the course of the discussion Dr. C. G. LAMBIE suggested the use of pilocarpine for the stimulation of the vagus, the advantage being that with this substance there was no increase of myocardial irritability.

Dr. A. R. GILCHRIST referred to the possibility of digitalis being a definite exciting cause of ventricular tachycardia and the danger of its use.

### *The Origin of Gall-stones.*

Prof. D. P. D. WILKIE stated that in years gone by the constant association of gall-stones and inflammation of the gall-bladder had led to the belief that catarrh was a necessary antecedent to stone formation. Modern study had shown that stones might exist without bacterial cause, and conversely inflammation might exist without stone. In the first type of case the usual stone was of the kind known as the "cholesterin solitaire," a large single stone of radiating structure, but with no lamellation. It was probably due either to an excess of cholesterin in the blood or to a disturbance of the bile acids holding the cholesterin of the bile in colloid solution. Whilst the single cholesterin stone might remain quiescent it was always possible that it might engage in the neck of the gall-bladder, thus giving rise to isolated afebrile attacks of colic. Infection was common in the gall-bladder, and in those organs thickened by chronic infection streptococci appeared with regularity even though the bile were sterile; the infection might come by the portal passages, the blood, or from some outside source, such as dental sepsis. In these cases there was great engorgement and thickening of the walls with symptoms of toxic absorption. The intimate connexion with the head of the pancreas nearly always gave rise to chronic inflammation at that site. Passing on to where stone and infection coexisted, Prof. Wilkie said that the former was probably the forerunner, impaction causing infection to take place followed by a secretion of mucus, which later became muco-pus. This might result in a mucocele of the organ, but more commonly the stone rolled back, re-entered, became mixed with the fragments of epithelium and muco-pus upon which cholesterin and bilirubin-calcium were deposited, and thus formed the nuclei of multiple stones septic in origin. At the same time a layer of pigment was deposited on the single stone forming the "combination stone.' At operation it was always necessary, no matter how many small stones existed, to search for and remove the large causal combination stone A primary cholecystitis was very apt to lead to calculus formation which might occur early or late by the same septic process, the swelling of the cystic duct shut off the gall bladder which filled with muco-pus, later when bile re-entered stones were formed Frequently at operations undertaken on account of symptoms which had led to the diagnosis of gall-stones, neither stone nor sign of inflammation was found These cases had been classified by John Berg into the two groups of muco-stasis and cholestasis, the former type of gall bladder being hypertonic, with mucoid contents, the latter being flaccid and filled with tarry bile, in both types stones were liable to form Westphal had attributed a functional cause to this condition, having proved that vagus stimulation causes spasm preventing the outflow of bile with biliary colic; this he called "hyperkinetic stasis." The reverse, "hypokinetic stasis, often took place in visceroptotic individuals. Here the gall bladder was thin walled and lax, often with pouching, this corresponded to the state of affairs produced by sympathetic stimulation In both these types stones might form later Biliary symptoms disappeared after the removal of the organ Considerable light was thrown on the origin of the numerous symptoms of gall bladder disease by study of the pathology and nerve-supply of the organ; the connexions of the nerve-supply accounted for the girdle pain, diaphragmatic arrest, and gastric flatulence The great absorptive power of the gall bladder explained not only its power of recovery, but also the acute systemic toxæmia in an acute attack and the slow poisoning in long-standing cases. Further, this absorptive power shielded the liver from bile pressure where the common duct was blocked, the same power was made use of in radiographic work. Gall-stones might be passed in relatively small numbers, but the gall bladder could never be cleared, nor could stones be dissolved in vivo Thus the only treatment was surgical This should be conservative so far as was permitted by the pathological state

Mr HENRY WADE, Dr FERGUS HEWAT Dr KEPPIE PATERSON and others joined in the discussion which in the main centred on the question of operation in cases of gall bladder trouble, whether it was preferable to operate early or to put the patient on diet and other treatment in the hope of the attack subsiding and the condition remaining quiescent.

Mr J W STRUTHERS demonstrated two specimens of intramesenteric diverticula from the small intestine occurring in cases upon which he had operated He described the cases and illustrated them by lantern slides. He said that these diverticula might give rise to acute conditions in the abdomen and their presence could easily be missed They were connected with the intestine by a minute canal which might become obliterated with the formation of a cyst

---

## ABERDEEN MEDICO CHIRURGICAL SOCIETY

A MEETING of this Society was held recently, Dr J CROMBIE, the President, being in the chair

Dr J CRAIG read a paper on

### *Acute Rheumatism in Childhood*

He said that the term rheumatism was unfortunate, but that we could now pick out a definite entity, a disease that works by successive recrudescences and reinfections and produces clearly defined clinical pictures. This condition was now called acute rheumatism, and was a general disease that had four chief manifestations: (1) carditis—when the heart is mainly affected, (2) arthritis—when the joints are affected, (3) chorea—when the brain is affected, and (4) subcutaneous nodules—when the subcutaneous tissues are involved These four chief phenomena, as one might expect in a general infection, often occurred together and in the young Invasion of the body by this disease was synonymous with invasion of the heart Many series of statistics could be given to show the seriousness of the problem. In 1925 13 5 per cent. of medical admissions to the Royal Aberdeen Hospital for Sick Children were cases of active rheumatism Those cases occupied beds for long periods, and the strain on the hospital accommodation was very great. Dr Craig discussed the ætiology of the disease in detail It was a disease of childhood, a little more frequent in girls than in boys, and more common in urban districts and in the artisan and labouring classes. The problem of the exciting cause was unsolved, and in his own opinion the real causal organism had not yet been found The essential pathology of the disease was one of focal nodules disseminated in the fibrous structures of the body In the heart these nodules were found specially about the central fibrous body He exhibited anatomical specimens showing this body and its intimate relationship to the valves. The mitral valve was clinically the one most affected, but the aortic valve was found to be more frequently involved than was clinically obvious. Stress was laid on the fact that the substance of the valve was affected—a valvulitis rather than a simple endocarditis In all the other parts affected the same nodules were to be found No special type of child was found to be the subject of rheumatism in Aberdeen The children were often nervous children but this nervousness might be due to the disease itself The symptoms were often vague, but the combination of pallor, languor, and wasting was suggestive The pyrexia, though often present at the onset of the active phase, was not a striking symptom Dr Craig dealt with the signs of carditis in some detail, and discussed the significance of an accentuated second pulmonary sound, of the so called reduplication of the second sound at the apex, and of mitral diastolic murmurs. Acute dilatation of the heart was the typical condition, and in Dr Craig's opinion pulse-rate charts were far more important than temperature charts. Subcutaneous nodules were found to be not uncommon in Aberdeen, 5 out of 30 cases showed them All the cases with nodules had marked involvement of the heart, and these nodules must be searched for, as they caused no pain and no symptoms; tonsillitis was common in Dr Craig's cases, but the rôle of the tonsil in rheumatism was somewhat difficult to define. Finally, the treatment was summarised. All the treatment centred on saving the heart, rest and patience being the most important factors. The length of the period of rest in bed was difficult to state generally, but it should be at least six months. *Homes for treating cases during convalescence* were required as accommodation for long periods could not be found in hospitals. The child should be kept at rest so long as the pulse-rate was falling and had not reached normal. So long as a recent mitral diastolic murmur was present the child should be kept in bed The child should be at rest so long as the physical signs were changing The child should gain in weight and in colour, and should have a healthy appearance, and when the child was allowed to get up the return to normal life should be gradual. At each progressive stage the effect of graduated exercise on the heart and pulse-rate should be noted In most cases, in Dr Craig's opinion removal of the tonsils and adenoids was necessary, but the removal had little effect on the rheumatism itself He held that the use of salicylates in treatment had been somewhat overrated

In a discussion which followed Dr WILLIAM BROWN, Prof ASHLEY MACKINTOSH, Prof R J MCKERRON, Dr J F. CHRISTIE, Dr A G ANDERSON, and Dr H R SOUPER took part.

# GENERAL MEDICAL COUNCIL.

*(Continued from p. 1150.)*

## REPORTS OF COMMITTEES AND OTHER BUSINESS.

### Executive Committee.

#### *Medical Reciprocity: Provinces of Saskatchewan and New Brunswick.*

*Saskatchewan.*—At the meeting of the Executive Committee in February last it was resolved to ask the Privy Council to take steps to rescind an order in Council which established medical reciprocity between Great Britain and the Province of Saskatchewan. A subsequent correspondence between the College of Physicians and Surgeons of Saskatchewan and the Registrar of the General Medical Council was read, but the position remains unaltered. The offer on the part of Saskatchewan to accept British practitioners registered in Great Britain if similar acceptance was granted to the diplomates of the Saskatchewan College was pointed out to be inequitable, because it would mean that, whereas a person registered in Saskatchewan and in the United Kingdom could practise, for instance, in Australia or in Italy, an Australian or an Italian, registered in the United Kingdom, could not practise in Saskatchewan. It was indicated that a reciprocal arrangement with the Dominion Council might get over the difficulty, but the Registrar of the Saskatchewan College wrote that the constitution and duties of the Dominion Council would not make this possible, while it could not be admitted that the General Medical Council should have any jurisdiction in the matter of arranging reciprocity between Saskatchewan and foreign countries.

*New Brunswick.*—A communication was made also to the Privy Council to point out that a decision communicated from New Brunswick on the matter of reciprocity represents the final conclusion of the Provincial Council, and that reciprocity has therefore ceased.

#### *Indian Universities.*

Colonel Needham made an oral report in regard to the present position of medical education in India, when the Committee resolved in the cases of the Universities of Bombay, Lucknow, and Punjab as follows:—

> "*That the recognition* of the degrees of M.B., B.S. granted until June, 1926, be continued until June, 1927, on the same conditions as before—viz., the receipt of a satisfactory report from an official inspector approved by the Council, stating that all the regulations of the Council are being fulfilled; and subject to the further condition that a statement be forwarded to the Council signed by the Dean of the Faculty of Medicine, containing a nominal roll of the medical graduates of the year, and a certificate also signed by him to the effect that each of them had fulfilled the regulations of the Council."

Communications were received from the Government of Bihar and Orissa forwarding an application from Patna University for the recognition of its degrees of M.B. and B.S. and enclosing the regulations of the University. These were referred to the Education Committee.

#### *Burma Medical Council and Medical "Cults."*

The Registrar of the Burma Medical Council desired guidance as to the recognition of the ethics of adding to the initials of medical degrees or diplomas letters signifying practice in homœopathy, osteopathy, chiropathy, psychotherapy, electrotherapy, and other "cults." It was pointed out that unregistered practitioners of "cults" have no legal status in this country, though there is nothing to prevent any registered practitioner from pursuing any theory of medicine in which he honestly believes, and nothing to inhibit a registered practitioner from consulting with any other person whose name appears on the Register, merely because the latter has adopted a special theory of medicine or surgery, such as homœopathy or osteopathy. As the additional letters were to be used on door-plates or otherwise in pursuit of publicity a note of warning was added.

#### *The Indian Medical Council.*

A copy of a Bill which has been introduced into the Indian Legislative Assembly and Council of State to "regulate medical education in India" was received.

#### *Dental Education and Examination.*

A report was received through Sir James Hodsdon, chairman of the Committee of Dental Education and Examination, on the observations of the statutory bodies concerned in regard to a previous report on the inspection of the qualifying examinations in dentistry and dental surgery. At the May session, 1925, a report on this subject from the Dental Education and Examination Committee was approved by the Council, who recommended that copies should be forwarded to the licensing bodies, together with the following resolutions, of the Council on Dental Examinations, when the bodies were asked for observations:—

1. That every subject included in the curriculum should form the subject of a written and oral or practical examination.
2. That two examiners should always participate in the oral or practical examinations of a candidate.
3. That whatever may be the system of marking, the percentage for a pass in each subject should not be less than 50 per cent.
4. That it is desirable that, where possible, the practical operative examination in clinical subjects should be conducted on the living subject, and should include dental prosthetics and orthodontia.
5. That it is desirable that, where possible, candidates should be tested in the administration of general anæsthetics in common use in dental practice, and should be required to perform extractions.
6. That the dental subjects of the Final Examination should be passed at one time.
7. That in the regulations for the several examinations it should be provided that examiners in assessing marks should be empowered to take into account the duly attested records of work done by the candidate throughout his course of study in the subjects of examination.
8. That a candidate remitted in any subject of a professional examination should before he is readmitted to examination therein be required to produce satisfactory evidence that he has, during the interval of remission, pursued, at a recognised medical school or dental hospital, the study of the subject in which he was rejected.
9. The candidates who obtain less than 30 per cent. of the marks in any subject should be remitted for a longer period than three months for further study in that subject.

At the November session, 1925, these observations were submitted and the following may be noted.

With regard to resolution 1—

At the University of Liverpool a paper in medicine is now included in the Final Examination for the Licence. At the Universities of Birmingham and Bristol and the Royal College of Surgeons of England courses of instruction in medicine are compulsory, but medicine is not a separate subject of examination in the Final Examination for the Licence.

With regard to resolution 5—

The University of Birmingham has adopted a recommendation "that candidates at the Final Examination for the Licence in Dental Surgery should be expected to administer nitrous oxide gas under the supervision of a qualified medical man, and to perform extractions under nitrous oxide gas or any other general anæsthetic."

The University of Dublin agrees with the remarks of the Royal College of Surgeons of England regarding the suggestion that candidates under examination should be called upon to administer anæsthetics to patients.

The Royal College of Surgeons of England states that "It is the practice of the examiners to ask questions relating to the administration of anæsthetics, of those candidates who are called upon to perform extractions under anæsthetics, and in the opinion of the Board it is not desirable to extend this part of the examination."

The University of Liverpool "does not approve of the suggestion that candidates under examination should be required to administer anæsthetics or to perform extractions for patients."

The Victoria University of Manchester considers the suggestions contained in the resolution (5) "to be neither practicable nor desirable."

At the National University of Ireland, Dublin, "students are not required themselves to administer *general* anæsthetics at the examination"

With regard to resolution 6—

The Victoria University of Manchester now requires that the dental subjects of the Final Examination be passed at one time.

From the replies received it appeared that the resolutions of the Council on dental examinations were enforced in the majority of cases

### FINANCE COMMITTEE.

The report of the Finance Committee was presented by Sir Holburt Waring, the Chairman. The report showed that the income of the General and Branch Councils for the year ending Dec. 31st, 1925, was £18,114 15s 9d The expenditure during the year was £12,189 3s 5d Consequently there was a surplus of £5925 12s 4d. The income was £127 less than in 1924, partly due to a reduction of £235 in the amount received for colonial and foreign registration fees, a source of income likely to be smaller in the future, and partly to an income-tax charge which is under consideration The receipts of the branches for registration fees show an increase in England of £437, a decrease in Scotland of £1010; and in Ireland of £30 The total number of registrations was 2500 as against 2706 The maximum has, therefore, obviously been reached and a considerable reduction may be looked for in the current year, and for some years to come.

The expenditure of the Council shows an increase of £1315, almost the whole of which is due to the fact that both sessions were prolonged, and they extended together over 13 days as against an average for the past five years of nine days. Besides this, the General Council had to break up over Whitsuntide, 1925, and reassemble, with the result that the fees of the Council show an increase of £720; printing of programmes, &c., an increase of £145; law expenses an increase of £244; and miscellaneous expenses an increase of £152 Against this increase there was a saving of £121 in fees paid to the Executive Committee, as there was no meeting in July Salaries show a reduction of £95 owing to changes in the staff, and house expenses of £94, due to a reduction in gas, electric light, &c.

The assets are increased by the surplus obtained by each of the branches—viz, England, £3960, Scotland, £1810, and Ireland, £612 The surplus of £5925 is £1258 less than in 1924 It is expected that the income of the General Council and branches will exceed the expenditure during the current year, but it is not likely that there will be a large surplus

The question of certain liabilities of the Council under schedules A and D has been listed for hearing by the Special Commissioners in July

### PHARMACOPŒIA COMMITTEE.

The report of this Committee was submitted by Sir Donald MacAlister, the Chairman The number of copies of the British Pharmacopœia, 1914, which was sold by the publishers between Nov 23rd, 1925, and May 28th, 1926, was 1080 copies. The number sold in the year ending May 28th, 1926, was 2384 This number is again greater than that for the preceding year The total number sold since the date of publication was 51 901 The stock remaining in the publishers' hands is 2031 copies.

The conference sanctioned by the Council on Nov 30th, 1925, was duly held on Feb 23rd 1926 There were present 23 delegates from the following medical, pharmaceutical, and scientific societies and bodies—namely: The Ministry of Health the Royal Society, the Royal Society of Medicine the Medical Research Council, the British Medical Association, the Physiological Society, the Chemical Society, the Linnean Society, the Pharmaceutical Society of Great Britain the Pharmaceutical Society of Ireland, the Pharmaceutical Society of Northern Ireland, the Society of Public Analysts. Opinions and criticisms were freely expressed on a number of points both of principle and of detail, and large questions were raised, such as the general organisation of expert committees of reference, the delegation of the Council's statutory powers and duties, the adaptation of the Pharmacopœia to Indian and Dominion requirements, and its relation to international and other agreements, and to therapeutic and pharmaceutical research On March 19th the Pharmacopœia Committee held a special meeting to consider the questions raised at the conference, and others bearing on the subject of the preparation of the next Pharmacopœia, and came to the conclusion that for the full elucidation of these questions it was expedient that an authoritative inquiry should be held, at which evidence of various kinds should be invited, and information not now in the possession of the Committee should be obtained

The Committee accordingly recommend in their report —

> "That the General Medical Council request the Lord President of the Privy Council to take steps for the appointment of a suitable committee, including members of the Council, empowered to make inquiries, to collect information, to receive evidence, and to make recommendations on the question whether it is desirable to make any, and if so what, alterations in the existing law or practice relating to the preparation or publication of the British Pharmacopœia and to its adaptation to the requirements of the British Empire"

### EDUCATION COMMITTEE

Dr J Y Mackay, the Chairman, placed the report of this Committee before the Council He said that it was long and required careful study It consisted mainly of the replies of the various licensing bodies to the inquiries circulated by the Committee concerning the steps which each body had taken to readjust its medical curriculum in accordance with the resolutions of the Council which came into force on Jan 1st, 1923, and the Committee recommended that it should be circulated to all these bodies for their mutual information

Dr H B Brackenbury, a member of the Committee, said that the matter was important, as many public authorities who carried out health services had complained that they could not find a number of sufficiently skilled private practitioners to assist them, especially in orthopædic work, in the treatment of diseases of the eye, and in certain aspects of children's diseases. Education authorities were establishing an increasing number of orthopædic clinics for their children and it often happened that one complained that no private practitioner in its neighbourhood was capable of doing the work If the Council, however, could say that the medical profession could supply a sufficient number of these practitioners it would not be necessary for local authorities to employ unqualified persons. There were two *difficulties* the first was that since the new curricula had only come into force on Jan. 1st, 1923, they had not yet had time to produce a practical effect on the body of the profession. The other was that the Education Committee had no power to inspect courses of instruction but only to visit at the time of the final examination and to see that proper questions were put The public demand for practitioners trained in these branches of medicine was very urgent and there must be no loss of time in meeting it, and although these matters might be trivial compared to some of the other work of the Council they were nevertheless important The Committee therefore relied on circulating their report to all licensing bodies to make those who fell short of the required standards realise their deficiencies The Council should also see what arrangements they could make to supervise training, as no time should be lost in making known to public authorities that students were actually being taught the curricula that the Council had laid down

Dr H H. Littlejohn, another member of the Committee, desired to dissociate himself entirely from the views of the previous speaker He said that licensing bodies were loyally carrying out the resolutions of 1922.

The President remarked that since many teaching bodies had anticipated these requirements of the General Medical Council a large number of sufficiently skilled practitioners was already available.

Sir W. L. Mackenzie said that in Scotland the Scottish Board of Health, which was the central authority with control over medical examination and inspection of school-children, of child welfare, of everything pertaining to tuberculosis, venereal disease, and the general public health, had never had any difficulty in the last 25 years in getting the class of young men and women that they wanted.

Dr. Brackenbury explained that although some authorities alleged that they could not find sufficiently skilled people he did not think that their allegations were well founded, but the Council should take care that they never became well founded.

Dr. Littlejohn agreed with Dr. Brackenbury's views as amended.

The Council resolved to accept the report unanimously and to circulate it to the licensing bodies.

### EXAMINATION COMMITTEE.

Sir Norman Walker, the Chairman of the Committee, submitted his report. Referring to the charts of passes all over the country he noted that the post-war crest had been passed in Scotland and Ireland, the returns in 1925 showing an abrupt drop. In England, however, the number (1246) was the highest ever reached, and he expected the drop to come this year. All the examinations in anatomy and physiology except that of the University of Wales have been visited. The results of the visitation had shown, said the report, that the Council might be satisfied that students were being properly examined. Licensing bodies differed slightly in their methods of examination in anatomy and physiology, but all satisfied the Council's requirements that these two subjects should be studied together and thoroughly understood together. The Committee, when visiting licensing bodies, had everywhere been received with the warmest cordiality, an eloquent answer to those who had predicted that the bodies would resent their interference. Everyone had been most anxious to show them everything that they could possibly wish to see.

The report of the Examination Committee was adopted, together with the following two recommendations:—

1. That the previous recommendation of the Committee adopted by the Council on June 2nd, 1920—viz.: That the licensing bodies which have not hitherto supplied in their annual return information as to whether they do or do not examine in operative surgery, ophthalmology, and mental disease be asked to do so in future—having served its purpose be discontinued.

2. That the Examination Committee be authorised to arrange for the visitation of the examinations in pathology and materia medica and pharmacology.

### PUBLIC HEALTH COMMITTEE.

Sir John Moore, the Chairman of the Committee, presented his report, which was adopted. He noted that the number of entrants for both parts of the examination had dropped from 465 and 456 in 1924 to 268 and 234 in 1925, by reason of the more rigid conditions which had come into force on Jan. 1st, 1924. It was gratifying that only five applications for exemption had been reported in 1925.

### DENTAL EDUCATION AND EXAMINATION COMMITTEE.

The report of this Committee was submitted by the Chairman, Sir James Hodsdon, and contained the observations of the licensing bodies in regard to a previous report of the Committee on the inspection of the qualifying examinations in dentistry and dental surgery. This report, together with certain resolutions of the Council on dental examinations, had been circulated to the bodies whose replies formed an appendix, giving a general view of the position of education along the special lines.

# Reviews and Notices of Books.

### MUSCULAR ACTIVITY.

By ARCHIBALD VIVIAN HILL, M.A., Sc.D., F.R.S., Professor of Physiology, University College, London. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1926. Pp. 115. 12*s.* 6*d.*

THE brilliance of any piece of research is displayed not only in the intensity and penetration of the light which it sheds into poorly illuminated zones, but in the continuity of ideas pervading it and the rigidity of the experimental proof supplied. The fascinating logbook which Prof. A. V. Hill has given us as the result of his cruise through seas for the most part unexplored and uncharted, has all these qualities in high degree. It consists of a course of lectures delivered by him in Baltimore in 1924, being the sixteenth course of Herter lectures. The first lecture deals with the dynamics of muscular activity. Here we learn that isolated muscle cannot be regarded simply as an elastic system, since the external work done when the muscle is allowed to contract against an inertia lever depends on the speed of shortening. Human muscle presents the same phenomenon, there being an optimum speed of shortening for each group of muscles, "a speed which everyday experience and common sense have led us to adopt in our ordinary working life." The system is, therefore, a visco-elastic one, and some of the visco-elastic properties of stimulated muscle have actually been reproduced by means of a simple model. One interesting and fundamental fact, which has been demonstrated on frog's isolated muscle, is that the tension of a stimulated muscle, when allowed suddenly to shorten, falls to zero and then reappears along a time course similar to that of the original development of tension. The fact that the degree of fall varies directly with the speed of shortening pointed to the subsequent redevelopment of tension, and hence presumably the original development of tension, as being determined by the visco-elastic properties of muscle. The true mechanical response is, therefore, probably much more rapid than the hysteresis curve to which we usually apply that term.

In the second lecture an account is given of the heat production of muscle under anaerobic and aerobic conditions. The delicacy of the recording apparatus, and the accuracy with which records of the time course of the heat production may be analysed, give us the only index at present available of the intermediate steps in that mechanism which is externally manifested in contraction and relaxation. These thermodynamic results, as Prof. Hill says elsewhere, provide a sketch only of the sequence of events; the completion of the drawing will rest with the chemists. Early experiments showed that the recovery heat production—i.e., the heat produced during the oxidative removal of some of the lactic acid formed in the initial stages of contraction, maintenance, and relaxation—was approximately equivalent to the initial heat; and since the oxidative removal of a given quantity of lactic acid would produce seven times the amount of heat that its production involved, it was clear that only a fraction of the lactic acid produced could disappear in this way. This fundamental conclusion, reached purely from myothermic experiments, has since been amply confirmed by Meyerhof's chemical analyses. Furthermore, the initial heat is absolutely independent of the presence or absence of oxygen. The lecture closes with a general account of the work of W. O. Fenn, one of Prof. Hill's distinguished pupils. We learn here that even an isolated muscle can, so to speak, feel the amount of work to be done required of it, and that the excess liberation of energy when a muscle is lifting a weight, over and above that liberated by an isometric contraction at the same initial length, is approximately equivalent to the external work done, "a fact which is very difficult to reconcile with the simple elastic body theory."

In the third lecture an account is given of the chemical changes accompanying muscular activity both in the absence and in the presence of oxygen. In the former case no changes other than the accumulation of lactic acid and its neutralisation have been discovered, and the absolute, and one might almost say uncanny, agreement between the observed heat of formation of sodium lactate from glycogen and base, and the heat formed when the same amount of lactate appears in muscle, is brought forward as an almost certain argument that other chemical changes are non-existent. The lecture proceeds with a description of the chemical changes occurring in aerobic contraction, and again the myothermic measurements are found to tally exactly with the energy exchange of the chemical events occurring under these conditions. A fascinating picture is drawn of the release of energy during short and prolonged stimuli, a picture which explains how the heat production of a single twitch is greater at a low than at a high temperature, whilst in a prolonged contraction the temperature coefficient of the energy liberation is positive. A fascinating calculation which shows that the surface tension theory of contraction cannot explain the large tension developed by the comparatively small amounts of lactic acid produced, brings the third lecture to a close.

In the fourth lecture we are given an account of the recovery process after muscular exercise in man. The facts discovered as a result of experiments on frog's isolated muscle are found to apply unreservedly to the case of man. We see how enormous may be the amount of lactic acid accumulated before exhaustion is complete, how the excess $CO_2$ liberated during and immediately following severe exercise is a measure of the lactic acid produced, and how the ratio of this to the oxygen used in recovery is a measure of the efficiency of removal of lactic acid, and therefore of the degree to which severe exercise may be sustained. The respiratory quotient of the excess metabolism of muscular exercise is found to be unity, just as in the case of frog's muscle. A striking calculation of the circulation rate from the oxygen intake during severe muscular exercise gives a figure as large as 8¼ gallons of blood per minute! And in order to perform this amount of work the heart would probably require 800 c.cm. oxygen per minute. From calculations such as these Prof. Hill suggests that "a deciding factor in the capacity of a man for severe prolonged exercise may often be the efficiency of his coronary circulation." The general medical public may not have had a very clear conception of the fundamental facts about muscular activity which Prof. Hill and his colleagues have demonstrated. The complete outline of the subject has been lucidly condensed into this volume, with many helpful analogies, and all are now in a position to appreciate the real knowledge that has been gained.

---

ANATOMY.

*Anatomie Medico-Chirurgicale.* By PHILIPPE BELLOCQ. Fasc. I, Le Crâne. Paris: Masson et Cie. 1925. Pp. 92. Fr.18.

Dr. Bellocq's treatise has the freshness of outlook and vitality of description usually to be found in the works of French anatomists. The book, which is apparently a series of lectures collated by Dr. A. Weiss and arranged by the author, bears the impress of its origin in the plan of treatment and in other ways. This volume deals with the head, excluding the central nervous system, and contains all the information anyone is likely to want on the structures found in this region. It is not a work on applied anatomy, but rather comes under the indefinite heading "medico-surgical" given to it on the title-page; it is difficult to draw a distinction between this and ordinary descriptive anatomy, unless the personal predilections of individuals are taken as standards of judgment; for surely a few references here and there to the bearing of certain facts on clinical matters do not afford sufficient ground for such a distinction. However this may be, Dr. Bellocq has produced a readable and interesting book, and we can look forward with pleasurable anticipation to the further issues of the series.

---

*Étude Anatomique des Artères de la Peau chez l'Homme.* By Mdme. PHILIPPE BELLOCQ. Paris: Masson et Cie. 1925. Pp. 63. Fr.12.

THIS is a summary of the results of radiographic observations on the cutaneous arterial supply. The subject is one which is only known from a general point of view, and a work such as this will find a place in anatomical records, and doubtless also in clinical regard. Madame Bellocq has shown how the arterial supply to various parts of the surface varies with age, and under certain mechanical conditions, and has classified the types which she has found and described. This little book is well worth reading.

---

*The Vertebrate Skeleton from the Developmental Standpoint.* By J. S. KINGSLEY, Emeritus Professor of Zoology in the University of Illinois. London: John Murray. 1926. Pp. 337. 21s.

AN excellent and authoritative account of the skeleton throughout the vertebrate phylum. The author bases his descriptions on the sound foundation of embryology, for, as he says, "only by ontogeny can homologies (or their lack) be ascertained in the various groups." Developmental details form but a broken path at present in this as in other walks of biological activities, but this does not lessen the truth of the view that they will ultimately make the only road of value, so far as can be foreseen at the moment. Prof. Kingsley has written a book which will be a work of reference on the subject for years to come. It is well produced, excellently illustrated, and provided with a comprehensive and useful bibliography which, while quite up to date, is not intended to be exhaustive.

---

APHASIA.

By S. A. KINNIER WILSON, M.D., B.Sc., F.R.C.P., Physician for Out-patients, National Hospital, Queen-square; Junior Neurologist, King's College Hospital. Psyche Miniatures Medical Series. London: Kegan Paul, Trench, Trübner and Co. 1926. Pp. 108. 2s. 6d.

Dr. Kinnier Wilson has written for the "Psyche Miniatures" Medical Series a booklet on the difficult subject of aphasia. In so short an essay it is, of course, impossible to treat this subject fully, but he has contrived to touch on many of its aspects and to present a succinct and lucid account of its manifestations and pathology. The introduction, which is really one of the most important chapters, deals chiefly with the nature of speech and its relation to thought; in it the author insists that the anatomical and physiological aspects of the study of speech and its disorders must not be separated from the psychological. "The function of speech is an intellectual function; the neural arrangements underlying its activity constitute a physiological mechanism; and the component parts of the latter have an anatomical localisation or site." These are the texts on which the subsequent chapters are developed. In the section on anatomical considerations, it is merely stated that "lesions within a more or less well-defined cortical region, extending from the posterior part of the lower frontal lobe, by the island of Reil, to the temporal and lower parieto-occipital areas, are likely to reveal themselves clinically by aphasia in one or other form;" the author, moreover, "regards it as amply proven that lesions towards the anterior part of the speech region are followed by aphasic symptoms in which defect of expression predominates and those towards the posterior part by aphasic symptoms in which the defect of reception is pronounced;" yet it is apparent that Dr. Wilson is prepared to go further in assigning subdivisions of the speech function to smaller areas. The next chapter considers the acquisition of speech by the child and the relation of the various simpler functions which go to make up the complex ability to understand written or spoken words and to recall words for use in spontaneous speech. The reader will regret that the need for brevity has restricted the space allotted to psychological considerations; the differences of intellectual and emotional and even "automatic" speech are mentioned and some emphasis laid on the frequent loss in aphasic patients of the feeling for grammar or syntax, but the chapter leaves us greedy for more detailed study by one who has obviously much more to say. The essay concludes with observations on some clinical types of aphasia and a note on treatment.

The booklet is excellent and we hope that the author will one day be moved to give us his views at greater length.

BEHAVIORISM.

By JOHN B. WATSON, formerly Professor of Psychology and Director of the Psychological Laboratory, Johns Hopkins University. London: Kegan Paul. 1925. Pp. 251. 12*s.* 6*d.*

THE fact that psychology deals with mental processes incapable of objective study places it, in the opinion of some people, outside the domain of science. The attempt is, therefore, often made to define these processes in physiological terms, but the results are unsatisfying both to the physiologist and the psychologist. Behaviourists boldly eliminate the difficulty by denying any usefulness or validity to such ideas as consciousness, memory, or instinct, and Mr. Watson builds up his theories of behaviour without resort to these conceptions. We must admit his possession of a bold and original mind, even though, unversed in behaviourist nomenclature, we cannot formulate the admission without introducing one of the concepts the writer has eliminated. Starting upon the physiological basis of unlearned activities and simple responses, he accounts for complex behaviour as a growth or development of these mechanisms. Memory, for example, becomes a repetition of manual or verbal habits, but thinking, "on account of the concealed nature of the musculature with which it is done, has always been inaccessible to unaided observation and to direct experimentation" (p. 191). Thus we are able to understand the author's meaning when he says, concerning habit formation: "I have had my own laryngeal processes stimulated to work upon the problem from another angle" (p. 166). Yet he sometimes gives way under the strain of maintaining behaviouristic terminology, and on p. 226 speaks in frankly subjective language of the happiness and contentment of the worker, though with a parenthetic explanation that he uses the terms as they are popularly used.

The behaviourist theory is an ingenious and fairly consistent attempt to circumvent the problem of the relationship of mind and body. Mr. Watson's presentation of it is to be accepted as a method of approach to psychology which is finding some amount of support in America.

ANTHROPOLOGY.

*Les Races et les Peuples de la Terre.* Second edition. By J. DENIKER. Paris: Masson et Cie. 1926. With 340 text figures and two plates. Pp. 750. Fr.75.

IT is doubtful whether the experts would consider this a sound summary of the present state of ethnographical knowledge, but for the ordinary reader it contains in a short space and with abundant illustrations an interesting collection of facts regarding the structure, manners, customs, and mode of life of men throughout the world. The correlation and interpretation of these data are notoriously ambiguous, and at the moment their historical and psychological significance are matters of active reconstruction and controversy with which the author does not concern himself at length. The first half deals in a general way with anatomy, houses and implements, psychology, social organisation, and so forth. The second half gives a systematic survey of the various races, and this should be useful as a dictionary in which to turn up any odd tribe which one may need to know more about. The footnotes give many references to the literature.

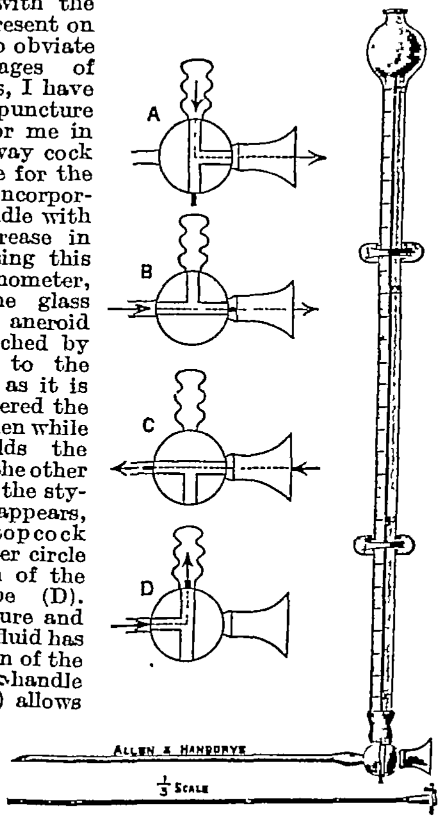
## A MANOMETRIC LUMBAR PUNCTURE NEEDLE.

THAT the pressure of the cerebro-spinal fluid is not measured in this country as often as it should be appears to be due chiefly to the difficulty of doing this single-handed with the apparatus at present on the market. To obviate the disadvantages of these apparatus, I have had a lumbar puncture needle made for me in which a three-way cock and a side tube for the manometer are incorporated in the handle with very little increase in weight. In using this needle the manometer, whether of the glass tube or the aneroid variety, is attached by rubber tubing to the needle as soon as it is felt to have entered the spinal canal. Then while one hand holds the needle in place, the other simply removes the stylet and, if fluid appears, turns the stopcock through a quarter circle in the direction of the manometer tube (D). When the pressure and pulsation of the fluid has been noted, a turn of the tap towards the handle of the needle (B) allows the fluid to run out of the manometer into the collecting tube and also allows further flow of fluid from the spinal canal. When the tap is turned away from the manometer (A) the manometer empties itself but the spinal canal is shut off. If it is desired to inject anything into the spinal canal, the tap may be turned towards the point of the needle, so that the manometer is shut off (C), but it may be though better to leave the manometer tube open, so that th injection pressure may be gauged and controlled. Th forward position of the tap may also be used fo replacing fluid with air. It is advisable to sterilis the needle with the stylet out, and with the tap turned towards the handle (B), as in that position water passes freely into the manometer tube from the inside of the needle. In the figure a glass manometer is shown, provided with two sliding clips, by which the initial and final levels of the fluid can be marked and read after the operation is completed.



Messrs. Allen and Hanburys, Ltd., of 48, Wigmore-street, London, W., are the makers.

## OSLER.[1]

THERE is a phrase in the Psalter, familiar to many from old association in connexion with Commemorations of Founders and Benefactors, a phrase which were it universally kept in mind would mean much for the happiness of the world *In memoria aeterna erit justus* To few men is this saying more applicable than to WILLIAM OSLER. Prof HARVEY CUSHING's excellent and fully detailed biography has already put on record OSLER's many activities and his wide and diverse fields of work, and has displayed him as ever striving for the good of his fellows and for the collection and dissemination of knowledge. But a further volume of Appreciations and Reminiscences of OSLER has its full justification, for it is only fitting that the Association of Medical Museums should wish to bear a prominent part in commemoration of one who from the start manifested the greatest interest in the organisation, and who called the first meeting of British medical men for the purpose of organising a British branch of that Association. So here we have a volume of over 600 pages containing appreciations and reminiscences of OSLER in practically every stage of his career

Most of them come from Canada, the country of his birth, the United States and England, the two countries where his professional labours were mostly carried on, but France speaks through PIERRE MARIE, Italy through MARCHIAFAVA, Germany through KARL SUDHOFF, and China through WU LIEN TEH (DR G L TUCK), Director and C M O of the Manchurian Plague Prevention Service It cannot be expected that the mass of papers contained in this volume should all be of equal merit, but one thing they have in common, and that is whole hearted and unstinted admiration of their subjects. The biographical section of the book covers 330 pages and is headed by an illustration of the coats of arms or seals of the five Universities which were the scenes of OSLER's academic activities—namely, Toronto, McGill, Pennsylvania, Johns Hopkins, and Oxford In regard to the arms of the last we note that the inscription in the book is not the familiar Dominus Illuminatio Mea, but the motto formerly in use, In Principio erat Verbum et Verbum erat apud Deum The first article in this section is a reprint of an address delivered by Dr NORMAN GWYN before the Medical Chirurgical Society of Montreal in November, 1920, which gives a delightful account of OSLER's immediate forbears, his father, and his uncle Edward, who was a medical man, and at one time a surgeon to the Swansea Infirmary EDWARD OSLER was interested in Marine biology and published sundry papers in Philosophical Transactions on Burrowing and Boring Marine Animals, exquisitely illustrated after his own drawings, some of which are reproduced on p 113 et seq This line of study showed itself inherited in WILLIAM OSLER when quite a boy, and was fostered by his admirable teacher, JAMES BOVELL, of Trinity College, Toronto Following the papers on Early Days are various papers and reminiscences by old pupils and others divided into sections dealing with the Montreal period (1870–84), the Philadelphia period (1885–89), the Baltimore period (1889–1905), and the English period (1905–19) All the reminiscences are interesting, and show the very varied characteristics of the man, one in particular, related by MARIAN OSBORNE, a relative of WILLIAM OSLER, in whose mother's house in Montreal he lived from 1871 onwards, when he was a professor at McGill University, is specially charming One day in the street he met a drunken old beggar who asked for alms. After some wholesome advice as to drink, coupled with a request that the old man should leave him his hobnailed liver, OSLER not only gave the man some money, but also took off his overcoat and gave him that too Two weeks afterwards the old man died in the hospital leaving a will in which he bequeathed "my hobnailed liver and his coat to my good friend WILLIAM OSLER." The coat, after disinfection, again passed into the service of the charitable physician. This episode is worthy of St Francis of Assisi, a saint whom in many ways OSLER resembled

And so the record goes on, a record of hard work, of helping lame dogs over stiles, of teaching and holding up to the younger generation an ensample of godly life, of sinking his own sorrows, especially that most bitter one of the loss of his only son in the war, in the Lethe of helping others, and of delight in books and their writers and of all real literary culture. OSLER's admirable Presidential address to the Classical Association in 1919 on the Old Humanities and the New Science perhaps better than any one of his numerous essays and public deliveries displayed his twofold qualities—his energy in aiding, encouraging, and restoring the sick to health, and his abiding joy in the words and the personalities of great thinkers. The facts so diligently and lovingly collected by Dr MAUDE ABBOTT make a volume worth the possessing

## "ESSENTIAL" HYPOTENSION.

ONE effect of the widespread employment of the sphygmomanometer by physicians has been the detection of a group of cases with a definitely low systolic pressure, apart from such well recognised causes of low arterial tension as Addison's disease, anaphylaxis, or myocardial weakness, to this group of cases the name of "essential" hypotension has sometimes been given. An appreciable literature has accumulated in the United States concerning these cases, of which the articles of RIESMAN,[1] MOSENTHAL,[2] FRIEDLANDER,[3] and BARACH[4] may be cited. A systolic blood pressure below 110 mm. Hg is usually taken as indicative of this condition. In 10,142 male subjects 279 cases of essential hypotension were noted, giving an incidence of about 3 5 per cent, but other observers have placed the percentage as considerably higher The symptom-complex said to result from the hypotension is one sufficiently familiar to all medical men, and yet so nebulous that the critical physician may well cavil at the verbal description of it. Dr

FOSSIER,[5] of New Orleans, in a recent communication, puts it in these words:—

> "Mental and physical fatigue are the predominant symptoms of essential hypotension, which, I think, can safely be attributed to the lowered arterial pressure. These patients tire easily, and it is with the greatest difficulty that they can concentrate attention upon their work. Memory is thereby impaired, so much so that these subjects are mental defectives, to the degree that they cannot perform the day's work of their more fortunate brothers . . . the intensity of their symptoms is alleviated in the recumbent position, and increased in the upright. Vertigo and headaches are frequently present. These subjects are, as a rule, hypochondriacs and neurotics . . . the extremities are usually cold, cyanosed, moist, and numb . . . the skin and conjunctivæ are pale and present an anæmic appearance, which is frequently diagnosed as some serious anæmia, but the blood is generally normal in its count and hæmoglobin content."

Capillary hypotension from histamine poisoning, decreased tissue-respiration, and exhaustion of the suprarenal glands are amongst the modern hypotheses advanced to explain this state. It is hardly necessary to add that the same disorder has enjoyed many previous explanations varying from nervous exhaustion to chronic intestinal stasis. FOSSIER, in the recent article we have already quoted, points out the extreme frequency of hypotension and this group of symptoms amongst splanchnoptotic subjects, and finds in the dropping of the diaphragm and consequent elongation and narrowing of the aorta the explanation of the decline in blood pressure; the hypotension is, he concludes, merely a symptom of the dropping of the thoracic and abdominal viscera. With such a conclusion we are inclined to agree, making the obvious reservation that it affords no explanation of the general ptosis. Loss of tonus is the outstanding feature of these cases, and whether this results from a disturbance of the normal outflow of impulses from the central nervous system, or whether it results from an intoxication of muscular tissues are questions still to be answered. The most important conclusion that can at present be drawn would seem to be that it is not upon any single organ that attention should be riveted; the stomach, or the heart, or the uterus, or the kidney may attract notice, but to treat one of them alone is to court disaster. Nor would it seem that excessive inspection of the vascular tension is likely to lead to dramatic benefit. The use of the phrase "essential" hypotension is, in fact, to be deprecated until our knowledge has been further extended.

◆

## VENEREAL DISEASE LEGISLATION.

IN the campaign against venereal disease strategy dictates the earliest possible treatment of the greatest possible number of persons affected. Success is to be attained, first, by organising the facilities for treatment, and, secondly, by inducing patients to take advantage of them. From these premisses the authors of a recent article in the *Bruxelles-Médical* proceed logically to the conclusion that, if any of these patients will not trouble to have recourse to treatment, there is both a right and a duty to employ compulsion. As the only method of compulsion is compulsion by law, they briefly review the present legal position in various countries and then formulate legislative proposals of their own. The three authors are Mr. CH. AUDRY, professor of the Medical Faculty at Toulouse; Mr. H. RAMET, first President of the Court of Appeal at Toulouse; and Mr. GABRIEL MARTY, an advocate of that Court. They cherish no illusion that mere legislation can bring in the millennium; they realise that public opinion must be considered in any proposal to which public assent is required; they do not expect to procure many convictions under their law, but they think it will bring pressure to bear where it is wanted, will lay down a necessary principle, and will arm society against a grave peril. They are primarily proposing their legislation for France; it is to fit in with the civil and penal codes of that country. The authors mention an enactment in force in Quebec, but have taken no account of the legislation of Great Britain. The English and French legal systems differ widely; nor is public opinion in England and France likely to coincide as to the form which legislation upon the subject of venereal disease should take. Nevertheless the proposed law is well worth examination.

It begins by confining itself to syphilis. Other forms of venereal disease, say the authors, are admittedly serious, but do not endanger the nation or the species. The English Venereal Disease Act of 1917, it will be remembered, applies not only to syphilis but also to soft chancre and gonorrhœ. In Clause 2 of what in England we should call their Bill the authors set out the duty of anyone who is attacked by syphilis to obtain treatment from a medical practitioner. Clause 3 proposes to enact that a doctor, called in to verify the existence of syphilis, must give the patient a notice advising him of the fact of his disease, of the risk of contagion and its duration, and of the penalties imposed by law on anyone who communicates the infection to another. The doctor is to obtain from the patient a written acknowledgment of this notice; he will endorse upon it the results of his inquiries as to the source of infection, and he is to keep the document in his possession for six months and must communicate it, if required, to the Procureur de la République. The patient, having thus received notice, is obliged to notify the departmental Conseil d'Hygiène on a prescribed form. Doctors infringing this provision, or officials violating professional secrecy, are punishable by fine of from 100 to 3000 francs, a second offence being punishable by imprisonment. Clearly the authors would have liked to take the more direct and logical course of making the doctor report the disease to the public authority, so as to make more sure of notification and so as to establish a comprehensive central record of great value in eradicating the disease. But they realise that this course (which has apparently been adopted by Sweden and Czecho-Slovakia) would antagonise professional traditions of secrecy. They therefore make the doctor merely the guardian of the document. He does not have to denounce his client, but is merely called in (in the event of a prosecution) by the judicial system of the country in order to give evidence of what English lawyers call the *scienter*. Presumably he produces in court the patient's written acknowledgment. If the patient duly reported his illness himself to the departmental health authority as proposed, the doctor's evidence will perhaps be unnecessary. Under Clause 4 a doctor who is prepared to certify that the danger of infection is over for a certain time can give the patient a certificate to that effect. This protects the patient from penal consequences for the period specified; but if there is infection during or after that period the patient must consult the doctor afresh. At this point there comes a group of clauses containing various penalties for communicating syphilis. Mere communication is visited by a fine of from 100 to 3000 francs, with imprisonment for a second offence. If a man who knows or ought to know the danger of his act exposes another person to the risk of infection the penalty is imprisonment for from six months to two years and a fine of from 500 to 3000 francs; this penalty is doubled if there has been actual infection. Deliberate infection is punishable with heavier penalties still. All the punishments in this group are to be doubled if the offender has failed to comply with the already mentioned obligation of obtaining treatment from a doctor. They are also doubled if the victim is under 15 years of age. If the offender is still a source of infection the tribunal may order him to be placed under treatment or medical surveillance for five months or more. A victim of infection is given the right to damages except when the risk of communicating infection was known and voluntarily accepted, but the action must be brought within six months. The tribunal can hear all cases in camera, but judgment must be given publicly, though the name of the victim (if the latter so desires) may be indicated merely by initials. A provision is added against blackmail. Another clause applies Article 463 of the Code Pénal, thereby enabling the judges to take into account extenuating circumstances and to mitigate penalties. Finally there is the usual administrative provision for making regulations and prescribing forms.

---

[5] A. E. Fossier: Amer. Jour. Med. Sci., 1926, p. 496.

Readers will have formed their own opinion as to how quickly we shall see any such law as this passed by the Parliament of the United Kingdom. Our existing legislation is characteristically piecemeal. We had, of course, in England the Public Health (Venereal Diseases) Regulations of 1916, directing local authorities to make schemes for institutional treatment and for the supply of salvarsan or its substitutes to medical practitioners, the local council being placed under the obligation to arrange to carry out the scheme as soon as the central authority approved it. Councils were also to arrange for local practitioners to obtain scientific reports on material submitted from suspected patients, and were permitted to provide for instructional lectures on venereal disease and for the publication of information as deemed necessary or desirable. Then in 1917 Parliament took the very practical step of restricting advertisements of remedies and prohibiting the treatment of venereal disease otherwise than by a duly qualified medical practitioner. The latter prohibition, it will be recalled, was to become applicable in local areas as soon as approved schemes for gratuitous treatment began to operate therein. Such schemes are gradually covering the country. Another useful enactment of a minor kind was the amendment in 1923 of the Merchant Shipping Acts, whereby the cost of medical attendance for masters and seamen was thrown on ship-owners (without power to deduct from wages) in the case of venereal disease as it was already in the case of other illnesses. We have admittedly no broad and comprehensive measure on the whole subject; there is a national hesitancy to examine the problem or even to recognise its existence. Possibly history will repeat itself and national legislation will be preceded by local legislation in certain progressive districts. Attention has already been directed to the Bradford Corporation Act of 1925. Section 68 applied the Infectious Disease (Notification) Act of 1889 to venereal disease, experimentally for a period of five years, in certain cases. Those cases are: (a) infants under 2 years of age suffering from such disease, and (b) persons (other than children) who refuse or neglect to undergo further treatment for such disease after being informed by a medical practitioner, or by the medical officer, that such treatment is necessary. The Bradford clause may be the forerunner of legislation of general application.

# Annotations.

"Ne quid nimis."

## RADIOLOGICAL INVESTIGATIONS ON THE ACTION OF PURGATIVES.

RADIOLOGY, besides having provided a noticeable contribution to the diagnosis and therapeutics of diseases of the digestive system, has still some important problems to take in hand from the point of view of physiopathology and pharmacodynamics, and not the least important of them is the action of various drugs on the tone and motility of different segments of the intestine. The literature on this subject has not been commensurate with its importance, and observations on the action of drugs on the intestines such as those of Magnus have been made only on animals. Prof. P. Alessandrini,[1] of Rome, has made a series of experiments on the action of saline purgatives and drugs of the anthraquinone group (cascara, phenolphthalein), of podophyllin, and castor oil. He used barium sulphate in preference to bismuth because the former has no influence on the rate of evacuation of the stomach and intestines, while, as has been shown by Best and Cohnheim, the latter causes a certain degree of retardation. The amount given was 100 g. in 300 c.cm. mucilage, and every patient was subjected to examination immediately and after repeated intervals up to 48 hours after the opaque meal. Normally the jejunum is full in the first half hour, and after about two hours the opaque meal occupies the ileum. The passage into the cæcum begins generally after the second hour, and after six or seven hours the ileum is empty and the meal occupies the ascending and as far as the middle of the transverse colon (Cannon's ring). After 24 hours the whole colon is full and at the end of 48 the meal is evacuated.

As a principle of physiopathology it may be affirmed that in order to produce a purgative action it is necessary that the purge should act on the colon, since a greater rapidity in emptying the stomach and small intestine may be accompanied by a greater stagnation in the colon. The action of various drugs, therefore, is expended either on the colon alone or on the colon and small intestines simultaneously. Under physiological conditions two zones exist in which stimulation induces an expulsive peristalsis. One consists of the cæcum and ascending colon, the stimulation of which determines the great peristaltic movement of Holzknecht, which originates in the cæcum and continues as far as the transverse and descending colon unless there is a spasm of the proximal portion of the transverse, the so-called Cannon's ring. The other consists of the ampullary portion and rectum, whose stimulation may provoke reflexly a large expulsive movement such as may be caused by a glycerine suppository or the very act of defecation. It is well established that saline purgatives are not only absorbed with difficulty but also prevent the water in the intestines from being absorbed, hence the contents of the colon are rapidly eliminated. The sulphates, moreover, produce a certain amount of sulphuretted hydrogen which acts as a stimulant to peristalsis. From his radiological experiments Prof. Alessandrini found that after the administration of 40 g. of saline in 250 c.cm. of water, in only one case was there caused a slight acceleration in emptying the stomach and small intestine, while in the other cases evacuation of these organs occurred normally, the gastric tone and peristalsis not being in the least degree modified. This would seem to show that the administration of small doses of sodium sulphate after meals in cases of gastric atony has no experimental foundation. So much the more that in the one case of slight acceleration noticed, the stomach showed feeble peristalsis and atony, and the acceleration was connected with a slight degree of pyloric insufficiency. On the rest of the intestines there was but a slight acceleration in emptying the cæcum and ascending colon, the principal action being expended on the second portion of the colon. This is confirmed by coprological investigations which show that the alimentary residua after purging with sodium sulphate are much less than with other purgatives. Consequently, as a reducing agent sodium sulphate is the least indicated as a purge. In four patients examined after the administration of Carlsbad salt (two teaspoonfuls in 200 c.cm. of water) there was in every instance a slight increase in gastric and intestinal motility; the chief action, however, was on the second portion of the colon and no doubt due to alkaline sulphates. This action of the sodium chlorides and bicarbonates in the Carlsbad salt justifies its use in chronic gastric intestinal affections; its action on cholecystitis is, however, doubtful.

---

[1] I problemi della Nutrizione. Giornale di fisiopatologia di clinica e di dietetica. May–December, 1925, Rome. Via san Nicolo da Tolentino.

In experiments with substances of the anthraquinone group (cascara, rhubarb, senna, and aloes) it was found that these were absorbed but slowly and incompletely; their purgative action is delayed because the decomposition which liberates their active principle (emodin) takes place but slowly. In large doses there was marked spasm with pain without, however, any indications of true inflammatory phenomena. Differences in the action of cascara and podophyllin are of some practical interest. Cascara invariably caused a certain retardation in emptying the stomach which lasted from one to two hours. This retardation was noticed also on the small intestine. Its action on the ascending colon was negative and was expended almost exclusively on the transverse. Usually the colon up to the splenic flexure filled normally; when the opaque meal reached this point there was active peristalsis and a complete evacuation in 10–12 hours after administration of the drug. This delayed action is due to the fact that the liberation of the active glucoside takes place by slow decomposition. On the other hand, podophyllin showed an acceleration in emptying the stomach and small intestine, the stimulant action on the peristalsis of the colon being manifest even on the proximal portion. Hence when it is desired to act on conditions of diffuse atonic constipation it is better to give cascara alone, provided that gastric atony is not also present. If, on the contrary, it is wished to act on cases of constipation of the ascending type especially associated with catarrh of the small intestine, then the preference should be given to podophyllin, which in small therapeutic doses does not give rise to any inflammatory action. When atonic constipation is associated with gastric atony it is advisable to combine cascara and podophyllin. Phenolphthalein, which by its chemical constitution belongs to the anthraquinone group, behaves differently in its therapeutic effects. It has the advantage, like all laxatives of this group, of not irritating the gastro-intestinal membrane. Its action in doses of 20 cg. is that, while it does not modify the rapidity of evacuation of the stomach and first part of the small intestines, it stimulates specially the peristalsis of the ileum and cæcum. Hence in constipation of the ascending type it is the ideal purgative, since moreover it does not cause pain and its action is manifest after three or four hours as soon as the gastric contents have reached the cæcum. Radiology disclosed some interesting facts regarding the action of castor oil, which acts especially on the small intestine without irritating it, by reason of the pancreatic juice which breaks it up into glycerine and ricinic acid. It was noticed, moreover, that there was always a retardation in gastric evacuation owing to paresis of gastric motility which, however, was regained after an hour. There was very rapid transit through the small intestine and throughout the whole length of the colon, being most marked in the proximal portion. This explains the efficacy of this drug in ensuring a rapid and complete evacuation of the whole intestine. Its continuous use, however, should be avoided on account of its harmful influence on the movements of the stomach.

These observations do not pretend to have solved definitely all the problems in relation to the action of various purgatives and the indications for their use, but they serve to show that radiological methods are valuable in the study of the complex questions of experimental pharmacology.

## LIME BURNS OF THE EYE.

Among industrial accidents to the eye lime burns of the cornea due as a rule to mortar or cement hold an important place, the resulting opacity being due not only to the actual destruction of corneal tissue but to the deposition of particles of insoluble calcium carbonate. A method of treatment founded upon the knowledge of this fact was recommended by zur Nedden at the Heidelberg Ophthalmological Congress in 1905, but although mentioned in Fuchs's, Römer's, and Parsons's text-books it does not appear to be generally known. Mr. E. Wolff, in the April number of the *British Journal of Ophthalmology*, in stating these facts gives details of two cases successfully treated, and tells us that the method is now in routine use both at University College Hospital and at Moorfields. The method consists of daily irrigation for a period of 15 minutes with a solution of 10 per cent. neutral ammonium tartrate. By this means the insoluble calcium carbonate is converted into the slightly more soluble calcium tartrate which is slowly washed away. In recent cases it is necessary thoroughly to cocainise the eye as a preliminary to treatment. In an acute case of this sort, in which vision was at first reduced to counting fingers, it was restored to normal after six weeks' treatment. In another patient who had already been treated for a month elsewhere the vision was improved from 6/60 to 6/12 after two months of the ammonium tartrate treatment. These successes should be noted by medical officers who work in industrial districts.

## PROFESSOR KROGH: A DEDICATORY VOLUME.

A collection of papers[1] of considerable interest and instruction to physiologists has recently appeared on the occasion of Prof. Krogh's fiftieth birthday, as the result of the wish of his numerous pupils and co-workers to acknowledge and commemorate the lasting debt owing to him as their teacher and friend. Dr. J. Lindhard points out in the preface that the occasion also marks the removal of the old laboratory in Ny Vestergade to the new building which will be erected by the Rockefeller Foundation for the purpose of Danish physiological research. "That removal will cause an increase of activity, but no other change. The delight in work which prevailed in the old place will never be exceeded, and the quality of the work will hardly be altered, but numerous students for whom there was not room enough at Ny Vestergade will now get their chance, and Krogh himself will obtain a suitable place of work, a convenience which he has of recent years only too often given up to others." The volume contains in all 22 papers of diverse nature, a few of which merit special attention. An account is given by Dr. L. S. Fridericia of work carried out by himself in the University Institute of Hygiene in Copenhagen, on the influence of the Jonas-Nielsen sterilising process on the A-vitamin content of milk. This process by which milk is brought rapidly to a temperature of 130° C., out of contact with air, and as rapidly cooled, was found to have comparatively little effect on the vitamin content, 3 c.cm. of the sterilised milk containing at least as much A-vitamin as 2 c.cm. of the same milk in the raw state. The results of this investigation form a useful parallel to those previously obtained by Gowland Hopkins, working with butter. Dr. H. C. Hagedorn communicates an interesting and valuable piece of work on the regulation of the blood-sugar. It is shown that whereas in the fasting subject there is no appreciable difference between the sugar content of the arterial and that of the venous blood, after ingestion of sugar the former runs for some time at a decidedly higher level than the latter. On the assumption that approximately half the right auricular blood has the same composition as that in the cubital vein from which samples for analysis are taken, it is found that almost the whole of the sugar ingested is absorbed in the periphery. In order that this observation may be brought into line with the known function of the liver as being a storehouse for carbohydrate, the hypothesis is put forward that alimentary hyperglycæmia covers two processes—viz., (1) a hyperglycæmia caused by the sugar which is carried through the portal vein to the liver, passes this and is deposited in large amount in the peripheral tissues; and (2) a hyperglycæmia caused by sugar carried to the peripheral tissue from the liver, but this transportation does not come into action until the absorption from the intestine has ceased or almost ceased.

---

[1] Physiological Papers, dedicated to Prof. August Krogh, Ph.D., LL.D. London: Wm. Heinemann (Medical Books) Ltd. 1926. Pp. 376. 30s.

Dr. G. Liljestrand and Dr. A. V. Sahlstedt contribute an important addition to the subject of gas diffusion through animal membranes. Using the frog's lung they find that the rate of diffusion of gases is proportional to $V^{\frac{2}{3}}$, where V is the volume of the lung, a result which was to be expected from mathematical considerations. Temperature changes, however, affect the rates of diffusion of $CO_2$ and of $C_2H_2$ in a very different manner, a change of temperature from 0 8° to 37° hardly affecting the rate of diffusion of $CO_2$, whilst causing a marked increase in the rate of diffusion of acetylene. These differences are so far unexplained on a physical basis, since in both gases a marked diminution in the rate of diffusion with rise in temperature was to be predicted. It is pointed out, therefore, that the solubility of each gas is probably very differently influenced by the components of the tissue forming the alveolar wall. Among other contributions of interest is one by Dr. Bj. Vimtrup on the structure of the Malpighian bodies in the human kidney. Though it has long been recognised that the glomerular tuft is divided up into several clusters of capillaries and that the visceral layer of Bowman's capsule is reflected into the spaces between these clusters, evidence is now brought forward that each capillary loop is covered, independently of the remainder, by a reflection of this membrane. The surface at which filtration may occur thus becomes very much greater than that which the more common histological descriptions of glomerular structure would have us believe.

The editors and publishers deserve congratulation on the collection in such attractive form of an interesting and stimulating series of papers

## THE DUSSELDORF MEDICAL EXHIBITION.

The great medical exhibition now being held in Dusseldorf may be fairly described as a medical Wembley. The word Gesolei, by which it is known for short, is compounded of Health (Gesundheitspflege), Social Welfare (Sociale Fürsorge), and Physical Culture (Leibesübungen), and here by every possible means these subjects are brought before the notice and imagination of the public. Prof. Arthur Schlossmann and his capable assistant, Dr. Liesegang, the moving spirits of the exhibition, are to be congratulated on the result of their efforts during the past twelve months. Here, illustrated by large-scale diagrams, maps, working models, and miniatures of hospitals, convalescent homes, health centres, and the like, are room after room and corridor after corridor filled with structures designed to illustrate every phase in the development of health insurance, public health, and preventive and curative medicine. The building and engineering trades have contributed their part and the result will interest public health officials, general practitioners, and social welfare workers. In Germany health insurance is compulsory for everyone with an income under £250 per annum, and voluntary subscribers are accepted over this level without income limit, with the result that private practice is said to have shrunk to 20 per cent. of its former extent. The great majority of German practitioners are, therefore, vitally interested in the proportion of insured funds which go to sick pay, maternity benefit, unemployment pay, maternity, hospital, and medical services. The visitor whose patience and stamina will bear the strain can learn all these things in one day at the Dusseldorf Gesolei. Relaxation is afforded by bands, restaurants, miniature railway, and the whole exhibition is picturesquely situated on the banks of the Rhine. The official catalogue in German contains 420 pages of letterpress and numerous plans, while shorter explanatory pamphlets in English are available. The exhibition remains open until October.

## THE LATE EFFECTS OF POISON GAS.

Before the Disarmament Drafting Subcommittee concluded its labours it adopted Lord Cecil's proposal that the Military and Economic Subcommittees should study the effects of poisonous gases used in warfare and give an opinion as to the best means of preventing their employment in future. In such an investigation the remote effects of any gas are as important as the immediate. The nature and the degree of permanent disturbance of the respiratory and other systems that may be fairly attributed to gassing during the war is still uncertain, though a large amount of material should be available for study in all belligerent countries. In America the problem is now being attacked by an attempt to investigate the present or recent condition of some 70,000 ex-Service men whose hospital records show that they have been gassed. The members of the Board appointed by the United States Veterans Bureau to organise the investigation include Dr. Philip B. Matz, Chief of the Medical Research Subdivision of the Bureau; Dr. A. K. Krause, Associate Professor of Medicine, Johns Hopkins University Medical School; and Lieut.-Colonel H. L. Gilchrist, Chief of the Medical Research Division of the Chemical Warfare Service, U.S. Army. The Board is not concerned with the better-known and more immediate effect of war gases. It particularly desires information on several points:—

1. Does any war gassing received in action result in disability which is relatively lasting and permanent?

2. Does it cause lasting anatomic (pathological) changes, with or without disturbance of function (symptoms and disability)?

3. What organs or systems may thus be permanently affected or disturbed?

4. What symptomatology may exist under these circumstances?

5 If war gassing does produce relatively permanent effects, may a similar condition or conditions be produced by other agencies (diseases such as influenza, tuberculosis, effort syndrome, &c.)?

The term "lasting" or "permanent," as used above, means such late residual or remote changes that continue down to the present time and are appreciable.

Those who are in a position to coöperate in the projected study by offering impressions from their personal experience are asked to communicate with the United States Veterans Bureau, Washington, where reprints of relevant articles will also be received with appreciation. The most difficult point in the questionnaire to answer categorically will probably be No. 5. If it be found that war gassing may produce relatively permanent effects, are these of a peculiar nature or might they equally well have been produced by other agencies? Symptoms or lesions produced by an individual chemical agent may easily be recognisable shortly after the time of injury, but after a term of years the body's healing process, which is essentially that of absorption and fibrosis whatever the nature of the insult to the tissues, is more than likely to mask their characteristics. The existence of a late lesion pathognomonic of gassing would have to be confirmed by its demonstration in a large number of human victims unless, of course, it could be substantiated by animal experiment. In the course of researches, published on p. 1192 of this issue of THE LANCET, on guinea-pigs exposed to the inhalation of mustard gas in a concentration of 1 in 20,000, Surgeon-Commander McCowen found histologically that the upper air passages, and the greater part of the bronchial tree, in addition to the lungs, were invaded by leucocytes in every stage of disintegration. After subcutaneous injections of the gas or applications to the skin the same invasion is seen at the sites involved, directly attributable to the intense reaction set up by mustard gas. Surgeon-Commander McCowen regards the increase in the hæmobactericidal power of the blood after exposure to this gas or to other tissue-destroying substances such as hydrochloric acid, formic acid, and liquor epispasticus, as due to release of antibacterial elements into the blood from disintegration of leucocytes at the site of damage. That the hæmobactericidal power of the blood is undoubtedly increased—the more severe the exposure the more pronounced the increase—is evident from the protocols of the experiments attached to his communication in the form of an appendix which space did not allow us to publish. This interesting observation, however, has little bearing on the problem of permanent effects, since presumably the blood reverts to normal in the course of a few days. But the histological study of the tissues, especially the respiratory passages, of guinea-pigs who have been exposed to the same concentration of inhaled gas and have survived for months or years might well throw light on the process of healing, of which the intense leucocytosis observed is presumably the first stage. The scarring may take some characteristic form which could be looked for in the autopsies of men known to have been gassed. By the correlation of such experimental findings with clinical observation it is at least possible that the Veterans Bureau may collect enough evidence to abolish gas warfare from among the weapons of civilised warfare.

## SOME EARLY AND LATER HOUSES OF PITY.

Dr. Hobson is already well known by his charming little Book of the Wandle (that rivulet whose defilement was eloquently mourned by Ruskin) and also as a protagonist in defence of Whitgift's Hospital, which some, unworthy of their inheritance, are anxious to pull down. In fact, the book now before us[1] grew from the desire of Dr. Hobson to write more fully than he had hitherto done about this hospital, and therefore to write about other hospitals prior to or contemporary with Whitgift's. The author says in his preface that his book owes much to Miss R. M. Clay's "Mediæval Hospitals of England" and still more to Dugdale's "Monasticon." He confesses that he has only made a selection from the many ancient hospitals and thus inevitably has left out something which somebody else thinks should be there. We for our part are surprised that Dr. Hobson has omitted any mention of St. Bartholomew's, Rochester, or rather Chatham, a foundation older than the better known house in Smithfield by some 15 years; it was founded before 1108, is still in use, and the original chapel remains. Neither does he describe the Spital of St. Katherine in Rochester, which is still in being; this foundation is comparatively modern, being founded in 1316. It is sad to see how many of these useful foundations fell on evil days, mostly in the great spoliation under Henry VIII., but some before this date owing, it must be confessed, to unworthy masters or governors. The original intentions of the pious founders were as nothing in the eyes of Henry VIII., of his bully, Thomas Cromwell, or of sundry commissions of later date, an admirable sketch of whose actions and the results thereof was given by Anthony Trollope in "The Warden." Dr. Hobson writes about Whitgift's Hospital and its archiepiscopal sister, Abbott's Hospital at Guildford, with a natural affection. We like his advice to his readers: "Go and see for yourselves, as, indeed, many do from all quarters of the world, including even some of the townspeople of Croydon." A whole chapter is devoted to the beautiful hospital (God's House) at Ewelme. This hospital, which was founded by William de la Pole, Duke of Suffolk, remained in the same family until 1525, when the last de Pole was killed at Pavia. Later on James I. annexed the mastership to the Regius Professorship of Medicine at Oxford, and until quite recently the Regius Professor of Divinity was ex officio rector of the parish. Dr. Hobson notes (p. 72) the statue of Alice de la Pole represented in her shroud, and gives a footnote by Mr. R. Hutchinson stating that these shrouded figures came in about the fifteenth century and lasted through Tudor times. Among the most notable existing ones is that of Dr. Donne, now in St. Paul's Cathedral, the only monument from the old building which escaped the fire. There are also fine examples in Maidstone Parish Church, being monuments to the Astley family circa 1600.

## CONTAGIOUS ABORTION.

THE organism which in the new nomenclature is called *Alcaligenes melitensis* lives naturally in goats and causes Malta fever when it infects man. The microbe *A. abortus* commonly lives in cattle and causes widespread losses of calves in this and other countries. The two species are extremely closely related to one another, and, apart from their pathogenic effects, the bacteriologist has to use his most refined serological technique to distinguish one from the other. Evidence has now accumulated that *abortus* may occasionally cause a vague febrile disease in man of the genus P.U.O.; some recent cases are described by Dr. I. F. Huddleson in America.[1] And it will, perhaps, be a surprise to many people to learn that English milk contains *A. abortus* quite frequently. In the last number of the *Journal of Pathology and Bacteriology*, the principal contents of which have already been summarised, Dr. G. S. Wilson and Miss Muriel Nutt, working in the Public Health Laboratory of the University of Manchester, narrate their discovery of this organism in about 8 per cent. of the samples of milk examined. This does not indicate any serious danger to human health; considering the amount of exposure to which cowmen must be subject, human infection is evidently very rare. But the recognition of its possibility will help to explain a few cases of obscure illness. The serum of a case of Malta fever will agglutinate both *melitensis* and *abortus*, and the serum from a case of *abortus* infection will, by the ordinary methods of testing, give a positive Widal reaction with both organisms too. Hence, presumably, come the odd examples of Malta fever which have been suspected to arise in this country. For it is now known that *abortus* antibodies can be found in a sensible proportion of samples of serum taken from children who have consumed cows' milk. And the probability seems to be that *abortus* in milk may actually be useful as a preventive of Malta fever; Khaled[2] showed that monkeys and goats can be immunised against *melitensis* by vaccination with *abortus*, and Nicolle suggested that this might be a useful method of human protection. The reverse can presumably also occur, and this may explain the old custom, more or less prevalent throughout Britain, of running a goat with a herd of cows to prevent miscarriages. Attention has several times been drawn to this.[3] Farmers have invented a variety of explanations of the habit; but the facts now known suggest at once that the goat acts as a prophylactic because the

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXXVII.—THE TREATMENT OF ANÆMIA.

### II. CHLOROSIS AND SECONDARY ANÆMIA.*

### (*a*) CHLOROSIS.

THE most remarkable fact concerning chlorosis is its almost complete disappearance within recent years. Obviously, the reason for its disappearance should reveal its treatment. The great improvement in conditions of labour, and the passing of the sampler and the "accomplishments" in favour of outdoor games among girls seems to afford the explanation. Chlorosis is probably induced by deficient oxidation during a period of active bodily development. Insufficiency of active exercise leads to lessened oxidation. The diminished oxidation leads to a less demand for the oxidising agent and the blood becomes poor in hæmoglobin. A vicious circle is thus established and the chlorotic girl becomes unfit for exercise. The theory that chlorosis is due to the wearing of tight corsets seems to be merely a part of the truth. On occasion the corset by interfering with respiration and by making exercise impossible may have played a part, but it may be said that the hockey stick and the fox trot have banished corsets and chlorosis together. A girl may suffer from over-work and fatigue and yet not become chlorotic. It is the lack of *active* exercise which is the important factor. The main difficulty to be overcome in the management of chlorosis is to stimulate oxidation in a patient who is unfit for exercise. Secondary difficulties are the poor and sometimes depraved appetite, constipation, and lassitude of mind and body. The object of treatment is not merely the removal of symptoms which may be relatively slight, but the removal of a handicap to physical and mental development at a time when these should be most active.

#### *General Measures.*

It may be a difficult question to decide whether a chlorotic girl is to be encouraged to take active outdoor exercise or advised to give up the attempt. A useful working rule is to keep patients in bed as long as the hæmoglobin percentage is under 60.

*Diet.*—The diet requires supervision. Chlorotic girls often prefer sweets and starchy food, and do not ingest a sufficient quantity of meat. Some firmness may be required in meeting this difficulty. Digestive troubles may require attention. An alkaline mixture combined with a bitter is often useful. Constipation must be dealt with. The most useful remedies are aloin and cascara.

#### *Drugs.*

Iron should be given, and given largely. The forms which may be employed are discussed in the section on secondary anæmia. It should be persisted with till the hæmoglobin percentage has reached 80. It is very much easier to treat a first than a subsequent attack, and a thorough recovery is less likely to be followed by relapse. Arsenic should not be used as a matter of routine, but it is useful in those cases in which the number of red corpuscles is materially reduced. Sometimes benefit follows the administration of digitalis, and this drug may be tried in cases not responding readily to iron.

#### *Prophylaxis.*

A sufficient amount of exercise should be taken to promote oxidation and to stimulate the formation of hæmoglobin. Over-fatigue, exhaustion, and bad hygienic surroundings, which impair the activity of the bone-marrow, either directly or indirectly, by making active exercise uncongenial or impossible, should be avoided. The prophylactic use of iron is worse than useless. In all ordinary circumstances enough iron for requirements is ingested with the food and more is useless. The large doses recommended in chlorosis act as stimulants, which do no good when not required and lead to diminished efficiency should necessity for their use arise.

### (*b*) SECONDARY ANÆMIA.

It may not be amiss to point out that before an attempt is made to treat anæmia it should be correctly diagnosed. Anæmia may be overlooked in persons who lead an outdoor life with weather-beaten faces. More frequently anæmia is diagnosed because of pallor. The pallor may be due to indoor life, aortic disease, or cardiac debility. The pallor that follows malaria is more often due to circulatory debility than to lack of hæmoglobin, although anæmia may be severe. It is therefore important to use instruments of precision before arriving at a diagnosis. The busy practitioner may plead lack of time to make blood counts, but it requires little time or technical skill to make a rough estimate of the hæmoglobin. It may be remarked in passing that the type, degree, and progress of anæmia can only be assessed with accuracy when full examinations are made. It is important that minor degrees of anæmia should not be allowed to obscure a more important condition. Such a case is the anæmic-looking girl with a tuberculous lung.

#### *Causes.*

It is important not only to diagnose anæmia, but to try to ascertain its cause. The most obvious is actual hæmorrhage, but if hæmorrhage is severe, its gravity is due to loss of fluid rather than to loss of hæmoglobin. The obvious indication is therefore to arrest the bleeding if possible and transfuse fluid. If the patient survives the initial loss of fluid he is still in danger from lack of blood, and the experience of the Great War proved that perfusion of blood is a more effective remedy that perfusion of saline solution. It is seldom that any of the blood diseases lead to massive bleeding. The hæmatologist is often asked to examine the blood to try to account for bleeding. The cause is generally to be found in such a condition as duodenal ulcer or uterine fibroid, and the anæmia is more commonly the result than the cause of the hæmorrhage. The bleeding of hæmophilia, purpura, and leukæmia is persistent rather than severe. It may be remarked that repeated hæmorrhages are specially dangerous. Occult bleeding should not be overlooked. Duodenal ulcer, intestinal worms, chronic dysentery, and piles deserve mention. Among other causes, bad feeding, poor digestion, sepsis or other toxæmia, albuminuria, and unhealthy surroundings are subjects for inquiry.

#### *General Measures.*

Granted that causal factors have been eliminated or mitigated, it is possible to treat a case of simple secondary anæmia after noting the patient's appearance, but it will add to the patient's advantage and the practitioner's interest if he will make an initial blood examination and repeat it at intervals of a fortnight. Patients with less than 60 per cent. of hæmoglobin should be kept in bed till that figure is reached. The diet should be light and nutritious. A little wine may be allowed as a stimulant to appetite, but the prescription is often more easily started than stopped. The old idea that red wines have any direct effect on hæmogenesis is fallacious.

#### *Drugs.*

*Iron.*—A depleted, overworked, or exhausted marrow can turn out red corpuscles faster than it can provide them with hæmoglobin. The expression of this is the low colour-index. Iron appears to act as a stimulus to the formation of hæmoglobin, and medicinal iron is not to be regarded so much a supply of iron as a stimulus to the utilisation of iron. It should be given in large, even massive doses if they are tolerated, and should be stopped as soon as the object of its administration has been attained. Blaud's pill capsules in doses of 10 gr., thrice daily, are very useful. The tincture of perchloride of iron is very efficacious, but not always tolerated by the stomach. Reduced iron when free from sulphur is excellent and the dose is small. The scale preparations contain too little iron to be of much use. Various forms of organic iron have been recommended, but no manufacturer has yet succeeded in inventing a sufficiently arresting name for his preparation to bring it into general use by a scientific profession. The products of hæmoglobin we have found useless. Some of the others are moderately useful, especially in cases with dyspeptic symptoms, but none are so good as the inorganic salts when they are tolerated. Hypodermic injections of iron have no special advantage.

---

* An article by Dr. Goodall on the Treatment of Pernicious Anæmia appeared in last week's issue of THE LANCET.

*Arsenic.*—Arsenic is often a useful adjuvant to iron. It is of special value when the number of corpuscles is low, and also in cases where the colour-index is high or tending to rise. Only small doses are required. The liq. arsenici hydrochlor can be given with iron. Tablets containing Blaud's pill and arsenic are convenient.

### *Other Measures.*

Circulatory stimulants sometimes seem to start a patient on the path to recovery. Horse serum may be tried hypodermically, or in doses of 10 c.cm. by the mouth. As was pointed out in considering this agent in the article on the treatment of pernicious anæmia, the patient should not be informed of the contents of the medicine if given orally or nausea may result. Sunlight, exercise, and massage are all desirable. Transfusion is not likely to be required in simple secondary anæmia. In post-hæmorrhagic cases it may be required. A hæmoglobin percentage of less than 15, a low blood pressure, and the availability of a suitable donor would be important factors in determining the operation.

## MEDICAL FACULTY OF EDINBURGH UNIVERSITY.

### BICENTENARY CELEBRATIONS.

THE celebration of the bicentenary of the foundation of the Medical Faculty of Edinburgh University took place on June 10th and 11th. The proceedings opened with the University dinner, which was held in the upper library of the old college on June 10th. Upwards of 200 members and guests attended. Sir Alfred Ewing, Principal and Vice-Chancellor of the University, was in the chair. After the toast of the King, the Chairman proposed the Guests in a speech which was certainly not the least happy of the many he was called upon to deliver during the celebrations. It was responded to by Prof. van der Hoeve, Dean of the Faculty of Medicine, University of Leyden; Dr. O. Robert Vaudescal, of the Faculty of Medicine of the University of Paris; Prof. Sir Humphry Rolleston, representing Cambridge University; and an old Edinburgh graduate, Dr. Andrew Balfour, Director of the London School of Hygiene and Tropical Medicine. The toast of the Edinburgh School of Medicine was proposed by Prof. Sir Archibald Garrod, representing the University of Oxford, and was replied to by the Dean of the Faculty of Medicine (Prof. Lorrain Smith), the President of the Royal College of Physicians of Edinburgh (Prof. G. M. Robertson), and the President of the Royal College of Surgeons of Edinburgh (Mr. Logan Turner). Sir John Rose Bradford, President of the Royal College of Physicians of London, proposed the health of the Chairman.

On Friday, June 11th, the Honorary Graduation took place in the McEwan Hall at 10.30 A.M., the proceedings having been opened with prayer by Prof. W. P. Paterson, D.D., LL.D. The Vice-Chancellor welcomed the 80 representatives of the universities and medical schools of Great Britain and Ireland, Copenhagen, Leyden, Manitoba, Oslo, Paris, Pennsylvania, Saskatchewan, Stockholm, and Toronto, who had assembled to do honour to the great Edinburgh school. The delegates greeted the Vice-Chancellor and presented their addresses. The Dean of the Faculty of Law, Prof. James Mackintosh, presented for the honorary degree of doctor of laws ten graduates of the University of Edinburgh who had, as he said, a common background of experience and tradition, all having been reared in the same medical faculty. In introducing them individually he spoke of the several ways in which each had brought credit to the school. The names of the honorary graduates are Dr. Andrew Balfour, Director of the London School of Hygiene and Tropical Medicine; Prof. R. Howden, Durham University; Prof. William A. Jolly, Cape Town University; Sir George Newman, Chief Medical Officer of the Ministry of Health, London; Prof. A. Primrose, University of Toronto; Prof. Sir John Robertson, University of Birmingham; Prof. Ralph Stockman, University of Glasgow; Mr. Logan Turner, President of the Royal College of Surgeons of Edinburgh; Sir Norman Walker, University of Edinburgh; and Prof. James T. Wilson, University of Cambridge.

After the ceremony Sir George Newman delivered an address on the history of mediæval medical schools, noting the revival of the Hippocratic tradition, and the rising fame of Leyden in the seventeenth and early eighteenth centuries. He traced the influence of Leyden on the development of the medical faculty of Edinburgh, congratulated the faculty on its past achievements, and predicted for it an equally brilliant future.

A short but impressive service held at St. Giles' Cathedral was made memorable to those attending by the beautiful rendering of the anthem ("God be in my head") by Walford Davies.

Luncheon followed in the Royal College of Surgeons of Edinburgh. Mr. Logan Turner presided, Mr. Alexander Miles acting as croupier. The loyal toasts having been honoured, the President proposed the Guests, Prof. T. Gillman Moorhead responding.

In the afternoon Sir John Gilmour, Secretary for Scotland, opened the reconstructed department of surgery, an account of which was given in last week's LANCET. The Principal of the University said that the appointment of a zealous young man to the chair of surgery had carried with it the obligation to try to meet his enthusiasm by giving him opportunities as regards time and space to organise surgical teaching and research. This obligation the Rockefeller Foundation had enabled them to fulfil, and the new surgical block was, he believed, unrivalled in the world. Sir John Gilmour spoke of the foresight and knowledge which had enabled the building to materialise, and expressed his gratification at being asked to open it. Prof. D. P. D. Wilkie, in moving a vote of thanks, said that unlike those in administrative control of certain other bodies of workers, his difficulty was not to exact certain hours of toil but to procure keys in sufficient numbers that any worker might be able to get access to the building to pursue his researches at any hour of the night. Workers in this department would include both intramural and extramural teachers. Indeed, the institute knew no wall but one—the wall of ignorance; breaches in this wall could be made only by continued and coöperative effort.

The delegates were entertained to dinner by the Royal College of Physicians of Edinburgh, Prof. G. M. Robertson, the President, taking the chair. Toasts included the town, to which the Lord Provost replied; the Faculty of Medicine, proposed by Prof. Tait Mackenzie, the Dean responding, and the President, proposed by Sir Alfred Ewing. A civic reception given by the Lord Provost, magistrates, and council concluded the celebrations.

The smoothness and dignity with which all the ceremonies were carried out under the wise guidance of Sir Alfred Ewing, Principal and Vice-Chancellor, impressed all the delegates, especially perhaps those representing less venerable institutions. They left Edinburgh heartened and stimulated by the signs of the deep influence that a big flourishing university can, in the course of time, exert on the life of a whole people.

## MEDICINE AND THE LAW.

### *New Dangerous Drugs Regulations.*

THE Home Office has given notice of its intention to amend the Dangerous Drugs Regulations in various important particulars, mainly in order to carry out recommendations in the report (issued last February) by the Ministry of Health Committee on Morphine and Heroin Addiction. Perhaps the most striking proposal is that of setting up a tribunal of three medical practitioners, assisted by a legal assessor, to decide charges of improper supply or possession of drugs against a doctor. At present the Home Secretary can, in cases of irregularity, withdraw a doctor's general authority to supply and possess, but he cannot do so until he has prosecuted the doctor under the Dangerous Drugs Acts and has obtained a conviction. As the Committee's report observed, when it is clear that in the interests of the public a doctor should lose his authority, it is undesirable that the Home Secretary should be obliged to chase him into the police-court to get a conviction. The mere withdrawal of the authority is often the appropriate penalty without the fines or imprisonment which a magistrate may inflict. Moreover, the issue in these cases is essentially medical—namely, whether the administration of the particular drug was or was not justified. It is therefore proposed to alter the regulations so that, if there is reason to think that a doctor is supplying, administering, or prescribing a dangerous drug to or for himself or anybody else otherwise than as required for the purposes of medical treatment, the Home Office shall be able to refer the case to the new tribunal. If the tribunal so recommends, the Home Secretary may, by notification in the *Gazette*, withdraw the doctor's authorisation and may exclude him from the benefit of the exception in Regulation 4 which allows the dispensing of drugs by doctors, dentists, and veterinary surgeons to be exempted from the general prohibition on supplying and procuring dangerous drugs. If the practitioner is thus excluded from the protection of Regulation 4, then he is definitely forbidden to give any prescription for the supply of such drugs. Regulation 5, which deals with the giving of prescriptions, is also to be amended. At present prescriptions must be in writing, signed and dated, &c., and must specify "the total amount of the drug to be supplied on the prescription." These latter words are to be elaborated into "the total amount of the morphine, cocaine, ecgonine, or diamorphine or any salt thereof to be supplied on the prescription, except that in the case of a preparation which is contained in the British Pharmacopœia, the British Pharmaceutical Codex, or the Drug Tariff issued by the Minister of Health for national health insurance purposes and which is not combined with any other preparation of any of the drugs not so contained, it shall be sufficient to state the amount of the preparation so contained." It is also proposed to add that a practitioner shall give a prescription only when required for purposes of medical treatment.

The Ministry of Health Committee devoted attention to the possibility of detecting cases where a patient obtains the drug of addiction from two or more doctors concurrently. With this object in view the Home Office proposes to amend Regulation 7. That regulation sets out the occasions when possession is not illegal. One of those occasions is when the possessor proves that the drug was supplied for his use by a medical practitioner or on and in accordance with a lawful prescription. The amendment proposed is apparently—for its language is not very clear—the removal of this protection for the possessor if he is under treatment from a doctor for addiction to any of the drugs or otherwise and is being supplied by a second practitioner and does not disclose the fact. Another change is to cause all doctors, dentists, and veterinary surgeons, if not already obliged to do so under Regulation 9, to enter in a separate register, in the case of each supply, purchase, or other obtaining of drugs, particulars of the date of receipt of supply, the name and address of the person, body, or firm from whom it is obtained, the amount obtained, and the form in which it is obtained. This will remove a doubt which has been expressed in certain recent prosecutions. A final proposal is that everyone authorised under Regulation 10 to carry on the business of manufacturing, selling, or distributing the drugs must keep them in a locked receptacle of which he himself or a qualified assistant holds the key.

It will be understood that these proposals are not yet law. The Home Office at this stage merely gives 40 days' notice (under the Rules Publication Act) of its intention to make these amendments. It has a statutory duty to consider any objections offered to the proposals, but is not obliged at the end of the 40 days to make the amendments, if there have been no objections, in the same terms as those which it has now advertised. The proposals appear to be a reasonable endeavour to implement the Committee's recommendations, though it remains to be seen whether they will work successfully.

### *Suicide as Murder.*

Last March a man who had been "keeping company" with a girl of 18 bought a small bottle of "lysol" disinfectant, apparently with the object that the pair should poison themselves and die together. Next day he and the girl drank the bottle. The girl died in hospital but the man recovered. He was tried at Liverpool Assizes on a charge of murdering her. As is stated in Stephen's Digest of the Criminal Law, "a person who kills himself in a manner which in the case of another person would amount to murder, is guilty of murder." It is further the law that, if A aids, abets, or counsels B to kill himself, A may be tried for murder. This is the result of Section 1 of the Accessories and Abettors Act of 1861, which enacted that anyone who becomes an "accessory before the fact" to a felony may be tried and punished in all respects as if he were a principal felon. At the trial at Liverpool the man was convicted; he applied to the Court of Criminal Appeal for leave to appeal against conviction. The ground of the application was that the judge directed the jury inaccurately upon the law of "suicide pacts." The judge had apparently stated that, if two mutually agree to commit suicide and accordingly take poison and one of the two dies, the survivor is guilty of murder. On behalf of the appellant it was objected that the statement was too sweeping; the survivor might have been forced into the suicide pact; the appellant, it was said, acted under the influence of the girl. The Court dismissed the application. The Lord Chief Justice observed that the man was with the girl at the critical moment; it was he who had purchased the poison; he had aided and abetted her. It was impossible to say that the summing-up was inadequate.

If the suicide pact were between husband and wife and the wife survived, she would, it seems, be technically guilty of murder. The Criminal Justice Act of 1925 (by a section which came into force on June 1st) abolished the old presumption that an offence committed by a wife in the presence of her husband was committed under coercion. The section adds, it is true, that actual proof that the husband was present and did in fact coerce his wife shall be a good defence on a charge against the wife, but this concession does not apply to offences amounting to murder. The new Act also alters the law of suicide by giving power to magistrates to dispose summarily of cases of attempted suicide instead of sending them necessarily for trial on indictment before a higher court. The new method (already applied in the first week of June to the case of a domestic servant who had taken poison apparently on being reprimanded by her mistress) is merciful and speedy and avoids unnecessary expense and publicity.

### *Duties on Obsolete Specifics.*

Year after year Parliament imposes excise duties upon a remarkable list of some 500 proprietary medicines and specifics more than a century old. The list begins with "Adam's Solvent" and ends with "Zimmerman's Stimulating Fluid." Already at the end of the seventeenth century the proprietors did not disdain alliteration's artful aid. There are pills, pastes and powders, drops, lotions, salves and essences whereof the very names breathe the atmosphere of romance or the suggestion of salvation "Birt's Martial Balsam," "Bourne's Ethereal Essence," "Hayward's Samaritan Water," "Ormskirk Medicine for the Bite of a Mad Dog"—the curious will find them all in the schedule to the Medicines Stamp Act of 1812. The list had been varied or re-enacted in 1802 and 1804, to go no further back into the mists of antiquity; but since 1812 there seems to have been no change. There the schedule remains upon the statute book by virtue of a few words in the annual Finance Act continuing the medicine duties as before. A year ago in the discussion upon the Finance Bill Captain Wedgwood Benn appealed to the Treasury to codify the Acts upon this subject so as to save the taxpayer the labour of antiquarian research. A sympathetic answer was given but nothing was done. Recently, on June 7th, Captain Benn renewed his appeal. In reply Mr. Ronald McNeill, the Financial Secretary to the Treasury, admitted that a drastic revision of the Acts was necessary. He added that it was intended in the near future to assemble an inter-departmental committee to examine the superfluity of ancient and obsolete enactments containing the specifics which are liable to medicine duty. He was able to instance the "Elixir of Longevity or Swedish Preservative," which is still mentioned in the statute book but which, though it may have been the cause of longevity in others, has not managed to preserve itself. The suggested reform is overdue. If such a list is necessary, machinery should be created for its revision from time to time with expert assistance. Were a list of 500 contemporary specifics to be compiled to-day from among our proprietary remedies how would it strike a reader in the middle of the next century?

---

**Puerperal Infection and a Nurse.**—At an inquest held on June 8th by Dr. M. H. Taylor, the Kingston coroner, on the body of a woman 33 years of age, death was recorded as due to puerperal septicæmia. The coroner stated that during the last six months he had held inquiries into the death of seven women from puerperal septicæmia who had been patients in the nursing home or attended by nurses of the Kingston Nursing Association. All the cases he had investigated, he said, had followed each other in such a way that there was no doubt that the infection was carried to the patients by the same nurse. He is reported to have added his opinion that 24 hours' quarantine was not sufficient in a case in which a nurse had been in contact with puerperal septicæmia. The Nursing Association's solicitor stated that the Ministry of Health had been approached with a view to an inquiry into the case.

# Public Health Services.

## RANGE OF MEDICAL SERVICE UNDER THE N.H.I. ACTS: TREATMENT BY CARBON DIOXIDE SNOW.

THE Medical Benefit Regulations define the range of medical service under the National Health Insurance Acts. The practitioner, they declare, is required to give his panel patients treatment comprising "all proper and necessary medical services other than those involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess." A question recently arose in Kent whether treatment of a verrucous condition of the sole of the foot near the first interdigital space by means of freezing with $CO_2$ snow was within the range of medical service. The Minister of Health, acting under Article 38 (4) of the Medical Benefit Regulations, remitted the question to referees, and the referees have answered it in the affirmative. The judgment of the referees states that the case was not urgent except that the verrucous condition was causing pain and lameness. The question was whether the process of packing the snow into the form of a "pencil" and its local application for cauterisation called for special skill or not. The Ministry contended that the skill required was no more than that involved in applying other forms of cautery—nitric acid, caustic, or electrolysis. No special training seemed necessary. Of the witnesses who supported the view of the Ministry Dr. H. B. Brackenbury and Dr. S. O. Pritchard had seen it applied once before they used it themselves; Dr. E. W. Adams had merely relied upon a friend's description, and Dr. Adam, Fulton upon a reference in a medical journal and upon the printed instructions. Dr. Gordon Ward, who appeared for the Local Medical Committee, submitted the contrary view. He called no witnesses but argued that the treatment did require special skill in seeing that the "pencil" was well rammed and compact and that its size was properly adapted to the size of the lesion, and in the degree of pressure to be exercised (over a bone or otherwise), the length of time of application and the discretion as to repetition. He made the further points that, the treatment being alternative to other forms of cautery, there was no particular reason to expect a general practitioner to acquire the necessary technical knowledge of it, and that many practitioners would not have acquired such knowledge before becoming qualified since the treatment was not introduced into this country until 20 years ago. In deciding the issue whether a particular service is one which involves special skill and experience, the regulations direct that regard is to be had to the question whether the service is one which is or is not usually undertaken by general practitioners practising in the same area. Dr. Ward addressed a questionnaire to 371 panel doctors in Kent upon this point with the following result: 46 per cent. said they were acquainted with the technique of treatment by carbon dioxide snow; 24 per cent. said they employed the treatment among their patients; and 18 per cent. said they possessed the necessary apparatus. These statistics did not prevent the tribunal from being unanimous in holding the treatment to be within the "range of medical service" which presumably expands from time to time but never contracts. The two medical members of the tribunal were Dr. G. Collingwood Andrews and Dr. John F. Walker; the chairman was Mr. E. H. Tindal Atkinson, barrister-at-law.

## SANITARY OFFICERS ORDER.

An Order issued by the Ministry of Health, which came into force on June 1st, reproduces in general the provisions of the Sanitary Officers Order of 1922, but prescribes some changes with regard to qualifications of sanitary inspectors. For the f the certificates of the Royal Sanitary Institu of the Sanitary Inspectors Examination Joint Board will be required, subject to the rights of holders of other certificates. A veterinary surgeon may be appointed a sanitary inspector for (say) the inspection of meat only, but the Minister expresses his opinion that such veterinary surgeons should possess a diploma in veterinary State medicine or have had special experience in practical meat inspection. The Order deals with both qualifications and duties and applies to all medical officers of health and sanitary inspectors appointed in the administrative County of London, but outside London only to officers whose appointing authority desires to recover half the salary from the county council or the Exchequer. In the case of a medical officer of health, it is apparently open to the appointing authority to make an appointment not to the approval of the Ministry by forgoing the repayment of the half salary for three years, at the end of which time the medical officer, unqualified by a diploma in public health, will have acquired a qualification by three years' service. There is general agreement that medical officers of health should be independent of the conflicting ties of private practice. Whole-time appointments can be readily secured by combining small districts or by adopting the Hampshire scheme of appointing county assistants to be local medical officers of health, or the Essex scheme of appointing local medical officers of health to carry out the county health services for their own district. The advantage of appointing whole-time veterinary surgeons, free of the ties and obligations of private practice, to carry out the provisions of the new Milk Act is also quite clear. If new legislation is needed to secure that all sanitary officers shall in future be fully trained for their work and devote their whole time to it, the sooner it is passed the better.

## REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics for 1925 of a group of districts of varying status. The death-rate from heart disease is stated separately, because of its direct bearing on the prevention of rheumatism in childhood, which is becoming a definite feature in the programme of up-to-date sanitary authorities.

| Name of district. | Estimated mid-year population (R.-G.). | Birth-rate. | Death-rates per 1000 of the population. | | | | | Death-rates per 1000 births. | |
|---|---|---|---|---|---|---|---|---|---|
| | | | All causes. | Tuberculosis. | Cancer. | Resp. diseases with influenza. | Heart disease. | Infant mortality. | Maternal mort. from childbirth. |
| Wiltshire C. .. | 295,800 | 16·7 | 11·2 | 0·68 | 1·60 | 1·6 | 1·8 | 53 | 3·3 |
| Reading C.B... | 93,670 | 16·1 | 11·1 | 0·92 | 1·28 | 1·6 | 1·5 | 56 | 4·6 |
| Barnstaple R.D. | 18,490 | 14·6 | 12·8 | 0·65 | 1·51 | 1·4 | 1·8 | 66 | 0·0 |
| Bridgwater B.. | 16,410 | 17·8 | 13·9 | 0·91 | 1·64 | 3·4 | 1·7 | 82 | 6·8 |
| Bognor U.D... | 12,800 | 13·6 | 9·1 | 0·39 | 1·10 | 1·5 | 1·7 | 34 | 11·5 |
| Chingford U.D. | 10,310 | 15·6 | 8·3 | 0·30 | —* | —* | —* | 43 | 0·0 |
| Stowmarket U.D. .. | 4,250 | 17·6 | 16·0 | 1·17 | 1·88 | 5·2 | 0·94 | 40 | 0·0 |

C. = County. C.B. = County borough. B. = Borough. U.D. = Urban district. R.D. = Rural district. —* = Information not in report.

### *Wiltshire.*

Dr. Claude E. Tangye tells us that social conditions and occupations are on the whole favourable to public health, and that, with the exception of Swindon, there is no approximation to the conditions of the manufacturing areas of the north. Urban districts [illegible] racter of country towns. Three diseases show special incidence, rheumatoid arthritis amongst farm workers, goitre amongst school-children, and pulmonary tuberculosis amongst factory workers. Overcrowding is still common, but deaths from infantile diarrhœa are comparatively few.

A considerable proportion of the metropolitan milk-supply is produced in this county, so that recent legislation considerably affects administrative activity. Prior to the end of 1925, five notices were received from the L.C.C. under Section 4 of the new Milk Act. There was difficulty in tracing the sources of infection, but ultimately, early in 1926, cows had been found giving tuberculous milk on four out of five farms reported, and in the fifth case the cow had probably been slaughtered before the receipt of the report. At first work under this Act was carried out by the veterinary surgeons appointed under the Diseases of Animals Acts, but now the county council has decided to appoint a veterinary surgeon for the Milk Act to serve the whole of the county, other than the area of his private practice. The Agricultural Committee of the county council granted three "Grade A" licences to producers during 1925, whilst the Ministry have granted two "Certified" and seven "Grade A (tuberculin-tested)" licences in the county. Dr. Tangye has no information as to "Pasteurised" licences, which are in the hands of the local sanitary authorities. The administration of the Meat Regulations, 1924, is fairly good in some towns and very lax in others. Producers with live-stock for disposal prefer the laxer districts. Dr. Tangye thinks sanction to the appointment of meat inspectors should be conditional on their holding proper qualifications. The Public Health Committee offered to provide free tuition in meat inspection at Bristol. Sixteen of the 35 inspectors were allowed to attend by their authorities, who paid their travelling expenses. Of the 16, six sat for the Meat Certificate of the Sanitary Institute and five obtained this qualification. Nine of the 35 inspectors now hold a qualification.

During the last five years five local authorities have installed modern bacterial sewage works and two more new schemes are in hand. In addition, three authorities have completed extensive alterations and improvements. The towns of Wiltshire have good water-supplies, but many of the villages "are dependent upon wells which have become hopelessly polluted, and others are dependent upon rain water only." During each of the last two years 12 cases of encephalitis lethargica have been notified and last year seven deaths resulted. The county laboratory has now been dismantled and bacteriological work for the county council is carried out at the Salisbury General Infirmary and the Royal United Hospital, Bath. Certified midwives attended 67·6 per cent. of the births in the county as compared with 66 per cent. during 1924. Dr. Tangye reports a remarkable decrease in "unqualified" midwifery practice.

### *Reading.*

Dr. H. J. Milligan's report is cheerful. The local occupations are not injurious to health. Infant mortality is lower than in most centres, although a little up in 1925 owing to whooping-cough. Health services are in a satisfactory state. An extension of the infectious hospital to provide 26 beds is in progress. There is provision for nearly every case of tuberculosis, usually without delay, the only want being accommodation for advanced female cases. Centres for maternity and child welfare work are established in every quarter, capable of meeting all demands. The municipal maternity home (13 beds) is to be improved by the provision of additional accommodation for staff and for isolation. The work of the antenatal clinic does not show a progressive ncrease, the new patients for 1925 (245) being two less than in 1921, 1923 being the "peak" year with 283 cases. Dr. Milligan's comment is that the midwives of the town ought to take more advantage of this clinic. The shortage of houses is still acute. At the time of the Census 2000 houses were occupied by more than one family and it is doubtful if the number has been much reduced since.

The large percentage of tuberculous milks found during the year is "a further argument for the use of designated milk from tubercle-free herds." Out of 35 samples examined six were found to contain living tubercle bacilli. The positive results affected five herds. In four cases the offending animal was found and slaughtered, and in the case of the fifth herd old beasts had been sold for slaughter after the taking of the sample. In 1925 the death-rate from tuberculosis reached a lower point than ever before, and Dr. Milligan is of opinion that the pavilion for the reception of advanced male cases is of special value. The water-supply is derived from the Kennet. The river water first undergoes coarse filtration and then fine filtration and chlorination to the extent of ½ to 1 part per million. Regular bacteriological examination shows that *Bacillus coli* is constantly absent in 100 c.cm. of the filtered water.

Practically the whole area is sewered on the separate system. Up to 1925 the sewage was pumped on to Manor Farm and distributed by broad irrigation, but the effluent discharged into the Kennet was not satisfactory. During 1925 an activated sludge installation was completed, but it is as yet too early to express a final judgment on the efficiency of the new scheme. The Education Committee has under consideration the extension of facilities for dental treatment and the provision of more commodious premises for the school medical department. Good results are still reported from ionic medication of ear discharges.

### *Barnstaple.*

Dr. J. R. Harper says a further improvement in the general health of the rural district and a more rapid diminution of tuberculosis is assured when the old cottage property has been replaced by modern and sanitary dwellings. The North Devon Infirmary, a modern hospital with an up-to-date X ray plant, is to open a maternity department within a few weeks. There is no hospital for infectious diseases, but the county council makes provision for small-pox. The Combe Martin water-supply problem has not yet been solved and is an urgent matter in view of the summer influx of visitors. The Woolacombe sewerage system has broken down several times during the year. The outfall becomes blocked and the sewer joints are forced. The sewer is privately owned. In August there was an outbreak of food-poisoning in a boarding house in Countisbury, affecting 35 persons and causing one death. The origin was traced to meat infected with *Bacillus aertrycke*, and after the lapse of three weeks a second outbreak affecting four persons was proved to be due to a member of the staff who had recovered but was a carrier of this bacillus.

### *Bridgwater.*

Housing is the subject of paramount importance in this ancient borough, the charter of which dates back to 1200, and Dr. G. W. Harvey Bird states that a programme of new buildings has been adopted and is being vigorously pushed forward by the council. A "great scheme" would be needed to deal with the narrow streets. Of the 24 infant deaths, which give an infant mortality-rate seven higher than that of England and Wales, 11 were due to congenital defects, eight to bronchitis and pneumonia, and two to whooping-cough. An effort has been made during the year to improve methods of milk production and distribution, but the council has had no applications for licences to produce designated milk. A demand for Grade A milk, distributed by a producer-retailer licensed by the Somerset County Council, is increasing, and this milk is supplied to the Isolation Hospital and the Baby Hospital.

### *Bognor.*

Dr. T. Philips Cole has laid stress in his last two reports to his urban district council on the importance of antenatal clinics, but up to the present expectant mothers have not appreciated the advantages offered. The water-supply is from deep wells about four miles north of the town and the water company are laying an additional service main to meet growing requirements. The sewerage service will soon require extension. At present the sewage is pumped to storage tanks, from which it can be discharged from one hour before to five hours after high water without polluting the foreshore. The extension can be dealt with in three ways—viz., by increasing the tank capacity, by keeping out storm and surface water, or by creating new works at the western end of the district. Since 1920 progress has been made in housing and the types of house most needed—viz., four and five-roomed houses—have been provided. Dr. Cole deals with the milk question at length. The veterinary surgeon inspects farms outside the district by consent. Since the Tuberculosis Order came into force he has been able to report 14 tuberculous cows to the county council, most of them with udders affected and two markedly emaciated as well. Bognor had a sunshine record for 1925 of 1885·5 hours, and claims to have a high percentage of winter sunshine when compared with the leading winter health resorts.

### *Chingford.*

Dr. Malcolm Barker mentions that a new sewage disposal scheme has been prepared by the urban district council and is under the consideration of the Ministry. This would take the place of the present sewage farm. The methods for disposing of refuse also have to be considered, owing to the rapid growth of Chingford. Between May 18th and June 30th a veterinary surgeon examined the 104 cows in the district. He took 23 samples of milk from individual cows with suspicious symptoms and 10 samples of mixed milk. The bacteriologist reported an excess of pus cells from nine cows, and five cows were removed from the milking herds. No tubercle bacilli were found in any of the samples, but no mention is made of the employment of the biological test or when the examination is to be repeated.

### *Stowmarket.*

Dr. S. O. Hounsfield says housing is the main urgent matter which requires immediate attention in this urban district. "Nearly all our cases of tuberculosis occur in these overcrowded, damp, or badly lighted and badly ventilated houses." Influenza and measles beginning in February, and the severe weather with more influenza in November, accounted for the very high death-rate from all causes and from diseases of the respiratory system.

---

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 5TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 219 (last week 193); scarlet fever, 1236; diphtheria, 749; enteric fever, 58; pneumonia, 1011; puerperal fever, 52; cerebro-spinal fever, 8; acute poliomyelitis, 2; acute polio-encephalitis, 1; encephalitis lethargica, 44; continued fever, 1; dysentery, 3; ophthalmia neonatorum, 122. There were no cases of cholera, plague, or typhus fever notified during the week.

*Deaths.*—In the aggregate of great towns, including London, there were 4 (0) deaths from enteric fever, 35 (8) from measles, 7 (2) from scarlet fever, 27 (2) from whooping-cough, 25 (8) from diphtheria, 40 (11) from diarrhœa and enteritis under 2 years of age, and 80 (9) from influenza. The figures in parentheses are those for London itself.

SMALL-POX IN BLACKBURN.—Two cases of small-pox were discovered in the Blackburn Poor-law Institution on June 7th, and further two cases on June 8th. Dr. O. M. Holden, medical officer of health for Blackburn, informs us (June 12th) that no more cases had as yet arisen in the Institution and no cases had occurred in the town. The notified cases were immediately removed to the small-pox hospital, all contacts were vaccinated to the number of over 500, and the Institution was closed to visitors. Daily inspection of all common lodging-houses in the town was initiated, and also a daily inspection of the houses of all residents who were in any way connected with the Institution. The source of the infection, Dr. Holden adds, has not been discovered, but it is suspected that it was brought in from an infected area by some casual, as all four cases had been inmates for several months.

# PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

## OPENING OF NEW PHARMACOLOGICAL LABORATORIES.

On June 16th the new pharmacological laboratories at 17, Bloomsbury-square, London, W.C., were opened by the Minister of Health.

The laboratories comprise four large and well-lighted rooms above the Examination Hall of the Pharmaceutical Society; additional rooms will become available as the laboratories develop. One room is at present used for the testing of the heart stimulants—digitalis, strophanthus and squill—and for research work. The next room contains, among other apparatus, that needed for testing the strength of pituitary extract and of the various preparations of ergot. A third room will be utilised if it is decided to add a vitamin-testing department to the laboratories. The remaining space is devoted to the housing of experimental animals in bright and hygienic surroundings.

### *The History of the Laboratories.*

The introduction of the Therapeutic Substances Bill into the House of Lords in 1924 indicated that there was a likelihood of standards being fixed for a number of therapeutic substances which could only be standardised by biological means and for which there were no standards in the British Pharmacopœia. The Council of the Society saw that the Bill opened up a field of work in which the Society might usefully participate, and decided to explore the possibility of equipping a laboratory in which some at least of the testing contemplated in the Bill might be carried out. The Ministry of Health and the Medical Research Council approved this project, and an Advisory Committee was constituted, including representatives of the Council and the Science Committee, the General Medical Council, the Medical Research Council, and the British Medical Association. Upon the recommendation of this Committee, the Council appointed as director Dr. J. H. Burn, of the Department of Biochemistry and Pharmacology of the National Institute for Medical Research, and the laboratories have been set up under his direction.

By the Therapeutic Substances Act (1925) any of the manufacturers who wish to prepare substances named in the Act must comply with certain regulations. The substances comprise (*a*) vaccines, sera, toxins, antitoxins, and antigens; (*b*) salvarsan and analogous substances; (*c*) insulin; (*d*) pituitary extract. Salvarsan can still only be manufactured under a licence from the German patentees. The patent rights, however, shortly come to an end. Similarly, insulin can only be made by those having a licence from the M.R.C. Pituitary extract may be manufactured without regard to patent rights. Arrangements are now complete for the testing of pituitary extract and of other substances considered by the Geneva Conference—namely, digitalis, strophanthus and squill, and ergot. It will be the aim of the laboratories to be able to accept for testing all substances which appear in the schedule of the Act, and in addition those which the progress of science indicates are likely to be included.

The laboratories were established with three primary objects: For research work upon the pharmacological testing of drugs, for training pharmacists in that work, and for the commercial testing of drugs for manufacturers. It will obviously be advantageous for manufacturers to take advantage of the facilities offered. The commercial value of a statement on the label of a preparation that it has been biologically tested by the Pharmaceutical Society of Great Britain, and has been found to correspond with a definite amount of a standard sample, does not need to be emphasised. The laboratories should be of value, in particular, to manufac[illegible]re unable to test their own products.

### *The Opening Ceremony.*

The President of the Society, Mr. P. F. Rowsell, in introducing the Minister of Health, said that so far the Society and pharmacists generally had not taken any very active part in the pharmacological testing of drugs. It was fitting, however, that the Society should take its share in this latest branch of medical science, especially since, with the institution of the Degree in Pharmacy by the University of London, the possibility of pharmacists with these higher qualifications undertaking this work became more clear and defined. The Society was responsible for the training and examination of pharmacists; it had always been its aim to ensure that training should be progressive, and that pharmacists should keep abreast of the changes which took place from time to time in medicine. The Society had been fortunate in securing as director Dr. Burn, whose vast experience in this work at the National Institute of Medical Research had placed the laboratories already in a position to test five classes of preparations.

Dr. Burn said that the service which the laboratories hoped to give would be based principally on the regulations of the Therapeutic Substances Act, in order that manufacturers might successfully comply with those regulations. The laboratories' smoothness of working was also closely connected with the Conference held at Geneva last year under the League of Nations. From time to time some manufacturing pharmacists had criticised biological testing as unreliable. The Geneva Conference had ended the state of affairs which justified such criticism. The guiding principle had been adopted of stating the result of a test on a sample in terms of the effect produced by a standard, and no longer in terms of the reaction of biological material.. Dr. Burn referred to the great part which Dr. H. H. Dale had played in the recent progress in biological assay. The Geneva Conference might properly be described as Dr. Dale's Locarno, since a body of internationally renowned scientific men might be just as intractable as a similar body of diplomatists. Criticism of biological assay had also been made by some medical men, who asserted that there was no evidence that the properties measured in the laboratory are identical with those required by the clinic. Work directed by Dr. Dale had produced a brilliant answer to the criticism in the case of both neo-salvarsan and of insulin. It had been shown beyond question for these agents that the laboratory test for potency was also a measure of the value to the patient. Dr. Burn expressed his hope that research would be the most important side of the laboratories' activities, since the imagination, the perseverance, and the enthusiasm inspired by research were of the greatest value in securing accurate biological assay.

Mr. Neville Chamberlain, Minister of Health, then declared the laboratories open.

# IRELAND.

(From our own Correspondent.)

### *Annual Meeting of the Irish Medical Association.*

The annual general meeting of the Irish Medical Association was held in the Royal College of Surgeons, Dublin, on June 9th, Dr. F. C. Purser, the President, in the chair. The Council had referred to the meeting a letter from the Irish Committee of the British Medical Association in which information was asked as to the present attitude of the Irish Medical Association towards it. The Irish Committee of the British Medical Association did not dispute the right of the Irish Medical Association to sever its connexion with the Irish Medical Committee, or to refuse to accept the resolutions of meetings of delegates, but it felt that it was due to the Irish branch of the British Medical Association, which possessed the largest membership of any medical association in Ireland, and in the Free State, that it should be informed formally of the decisions of the Irish Medical Association, so that it might, in the circumstances, be in a position to seek independent representation.

Senator W. O'Sullivan, Past President, proposed, and Dr. T. B. Costello seconded a resolution—

> That, in matters in regard to legislation affecting the interests of the medical profession in Ireland, it is advisable that the opinion of the profession should be expressed by an organisation representative of the entire profession, and in present circumstances this can best be done by the Irish Medical Committee.

After considerable debate the President, on consulting the standing orders, ruled the resolution ultra vires. The annual report of the Council was then presented. It was stated that the membership at the end of last year was 431. The accounts showed a balance in hand of £610. The result of the annual election was declared, Dr. Purser being re-elected as President and Dr. H. T. Warnock as Vice-President. Several committees were elected and the meeting adjourned.

Dr. Purser, the President, in his address, spoke of several matters of medico-political interest which had been engaging the attention of the Association during the past year. He believed that the scheme for medical registration and control in the Saorstát would be found to satisfy most people. The Executive Council had given the representatives of the profession a very fair hearing. Ample opportunity had been given for expression of views on every aspect of the controversy and even minor details had been considered without haste or hurry. The details of the scheme were still private. The Bill giving the selection of candidates for Poor-law medical appointments to an Appointments Commission was of the utmost importance. It was welcomed by this Association, for not only did it strike a blow at corrupt practice in elections, but it put the assessing of merit into the hands of those best qualified to assess it. Further, it would be welcomed as a step towards a State medical service, as it removed the chief stumbling-block in the way—namely, patronage of local authorities. It was greatly to be regretted that the system of graded salaries had not been adopted in all counties. In co. Mayo, for instance, the salaries paid were much below the salaries in the neighbouring and equally poor county of Galway. Urgent representations had been made to the Minister for Local Government d Public Health in this matter, but so far he uld not be induced to exercise pressure to remove is injustice.

### *The Local Authorities Bill.*

The Local Authorities Bill passed the Dail last ek without any serious modification, and it is not ely to be changed in the Senate. By this Bill l appointments (other than by promotion) under cal authorities will be made on the recommendation a special "Appointments Commission," who will, all cases other than technical or professional ppointments, make their selection by the method of mpetitive examination. A strong fight was made carry an amendment to the effect that the Appointents Commission should send a short list of itable candidates to each local authority, with hom the final selection would rest. This was defeated y a large majority.

### *Royal College of Surgeons in Ireland.*

The annual elections of the Royal College of urgeons in Ireland have resulted as follows:—esident: Andrew Fullerton. Vice-President: homas E. Gordon. Secretary: Sir F. Conway wyer. Council: Sir Thomas Myles, Sir Arthur hance, Sir Robert H. Woods, Richard Lane Joynt, r William Taylor, R. C. Butler Maunsell, Sir W. de C. Wheeler, Sir F. Conway Dwyer, Trevor Smith, Sir C. Arthur K. Ball, Louis A. Byrne, ton Pringle, Edward Sheridan, Adams A. McConnell, R. Atkinson Stoney, William Pearson, George E. Pugin Meldon, Howard Stevenson, Sir William J. Smyly. The new President, Mr. Fullerton, is surgeon to the Royal Victoria Hospital, Belfast, and professor of surgery in Queen's University. He was consulting surgeon in the Boulogne area during the war, with the rank of colonel in the Army Medical Service, and received various decorations. This is the first time that a Belfast surgeon has been elected to the Presidency of the College, and the first time for many years that any provincial surgeon has received the honour. Mr. Gordon, the new Vice-President, is surgeon to the Adelaide Hospital, Dublin, and professor of surgery in Trinity College. Both Mr. Fullerton and Mr. Gordon were elected without opposition.

---

## NATIONAL INSTITUTE FOR THE DEAF.

THE annual meeting of the National Institute for the Deaf was held at the Mansion House, by the kind permission of the Lord Mayor, on Friday, June 11th, when Lord Charnwood presided over a large gathering. The report was read by the secretary of the Institute, Mr. A. J. Story; it showed that since the brief period following upon recent reconstruction the work of the Institute had been successfully carried on and that large provinces of future endeavour had not only been outlined, but a promising commencement of activity had been made. The directions of the work as shown by the report included coöperation with the necessary authorities in securing the expert medical attention and advice necessary to obviate improper classification of deaf subjects as mentally unsound, and especially for the inquiry into the condition of deaf children who are too often believed on account of their physical defect to be mentally deficient and so wrongly categorised. The report also showed the many directions in which deaf subjects, if educated, could be employed to their own advantage and that of the community, and disclosed the need for public pecuniary support.

Lord Charnwood, in moving the adoption of the Report and Accounts, emphasised the fact that the Institute was the only body attempting to coördinate and correlate the work of the many institutes, agencies, and centres that had been started, mostly of recent date, to improve the welfare of the deaf, to educate them so that the one barrier between them and their fellow citizens should be at least partially thrown down, and to secure for the many competent deaf people employment despite their disability, which in so many cases should not really be considered a handicap.

The adoption of the report was seconded by Sir Squire Sprigge, who analysed the reasons why the deaf population did not secure the proper amount of public sympathy. He pointed out that medicine was now having considerable success in the prevention of deafness by the early and appropriate treatment of the sequelæ of infectious diseases, and he believed that the medical profession would welcome the opportunities offered to associate themselves with the work of the Institute, especially in the task of inspection, so as to guard against wrongful diagnoses among the sane of mental abnormality.

The adoption of the report having been unanimously carried, the Duchess of Atholl proposed:

> "That this meeting, interested in the welfare of the deaf, desires to call attention to the many and severe handicaps in the lives of those who suffer from deafness; and earnestly commends the work of the National Institute for the Deaf and that carried on by local societies for the deaf in some 70 districts of the United Kingdom to public sympathy and support."

She outlined the claims for public sympathy with the deaf, and speaking from experience at the Board of Education, she reminded the meeting how much good had been done by the treatment of early ear troubles, and, therefore, in the prevention of deafness, through the systematic attention to the ears of the school population.

The resolution was seconded by the Dean of Westminster and was unanimously agreed to.

A resolution was then proposed by Lady Robson as follows:

> "That whereas deafness overtakes large numbers of persons in adult life with the result that many of them become deprived of their employment, this meeting begs employers to consider whether by adjustments of staff they can retain such persons in their service and thus prevent the addition of the burden of idleness and want to the already heavy burden of deafness."

This, which was seconded by Sir Harry Stephen, was also agreed to unanimously, and the meeting closed with a vote of thanks to the chairman.

## THE QUESTION OF SPECIAL DIPLOMAS.

*To the Editor of* The Lancet.

Sir,—From time to time vacancies are advertised in the columns of the medical journals, one of the conditions of candidature being the holding of one of the special diplomas. We learn that the D.P.H. is an extremely useful additional qualification, the possession of which is indispensable to those who wish to become school medical officers or medical officers of health. The D.T.M. is almost compulsory to would-be officials of the Colonial Medical Services or workers in the tropics, special pay being promised to the holders of this extra qualification in many cases; and it is useless to try for any tea- or rubber-estate appointment without it. The possessors of the D.M.R.E. hold the fort as regards vacancies on the electro-therapeutic or radiological staffs of our large hospitals and institutions, and the D.P.M. has become the sine qua non for all who propose to specialise in mental or nervous diseases and whose intention it is to get on the staffs of our large asylums. Diplomas in tuberculosis diseases—i.e., D.T.D.—are now expected of tuberculosis officers, and further special courses and qualifications are now being advanced for bacteriology and every other side line in medicine and surgery.

The question now arises—why are these demands being made? The answer is surely, that the holders of these special diplomas are recognised by the various authorities as being more highly qualified or specialised to hold certain posts than could be those medical men who are not so trained. This being a fact, how is it that these qualifications with one exception—i.e., the D.P.H.—are not registrable. It does not appear that those responsible for this oversight quite realise that it not only takes time and money, but an intensive training and stiff examinations before these diplomas are obtained, and that they are only granted by recognised examining boards and universities. Why, then, should these diplomas remain officially unrecognised? Who is responsible? What antiquated machinery refuses to move? It is quite time that all qualifications legally gained by hard preparation and after due examination should be registrable as "extra qualifications," providing the holders are already qualified to be admitted to the Medical Register.

I do not know of any actual hardship which has accrued to the holders of these special diplomas on application for posts owing to the fact that special diplomas cannot be registered, but it is clear that serious inconvenience may arise and probably has arisen. For example, a medical man when travelling applies for a vacancy and his personal statement of possessing a diploma is rightly not accepted, yet no one usually carries his diplomas about with him. The possession of a non-registrable special diploma may be supported by an entry in the Medical Directory, but absence of its registration in the Medical Register, the official roll of the profession, might make it necessary for an applicant to prove his identification and statements. Employers recognising the value of these special qualifications often demand them, even when not obliged to do so by the rules which govern the appointments, and are put to extra trouble and correspondence to ascertain that an applicant has the special training required, and this only because he is not registered as holding some diploma which he claims to possess.

I can quite understand that new legislation is necessary to set this matter right, and it seems to me that the initiative might well come from the statutory bodies which grant the diplomas. A few weeks ago the Society of Apothecaries was told that the right to grant a registrable diploma in midwifery could only be acquired by legislation, so that the situation should be clear to all the statutory bodies. There is also support for the reform to be found in the fact that degrees taken in special branches of medicine—i.e., M.D. (State Med.), M.D. (Trop. Med.), and M.D. (Psych. Med.)—are registered; if the degrees why not the diplomas?

I am, Sir, yours faithfully,

C. Russell Corfield, M.D. Brux.,
L.M.S.S.A. Lond., D.T.M. Liverp.

Lincoln, June 14th, 1926.

*** We have reason to believe the General Medical Council is perfectly willing to register the special diplomas but little enthusiasm has been manifested by the statutory bodies issuing them to press for the new legislation which would be necessitated. The D.P.H. is registrable by the Council whose ruling on the cognate curriculum is therefore binding on the educational bodies concerned. Some of these might object to loss of autonomy in the matter of special diplomas at present non-registrable. In regard to these the Council as the authority on medical education may pass resolutions but the examining bodies are not bound by them.—Ed. L.

## X RAY TREATMENT OF CANCER.

*To the Editor of* The Lancet.

Sir,—In the leading article on the X Ray Treatment of Cancer in The Lancet of June 12th, you were kind enough to make some references to my recently published book on "Radiotherapy in Relation to General Medicine" (Oxford Medical Publications). One quotation is: "To British radiologists the treatment of carcinoma of the womb is of little practical importance, for they never see it." Your inadvertent omission of the word *early* before *carcinoma* (see p. 97) might perhaps lead readers to believe that radiotherapeutists in this country take no interest in uterine cancer. The contrary is the case. We do our best for the inoperable and the recurrent cases, of which, unfortunately, there is a plentiful supply. Control of pain and hæmorrhage is usually possible, and in some instances restoration to apparent health for a period measured in months and occasionally in years.

I am, Sir, yours faithfully,

F. Hernaman-Johnson.

Harley-street, June 12th, 1926.

## "TOXIC (SUBDURAL) MENINGEAL HÆMORRHAGE."

*To the Editor of* The Lancet.

Sir,—We should like to thank Dr. C. P. Symonds for his comments in your issue of June 5th and to submit the following observations in reply:—

In the first place we agree that the term "subarachnoid" is a more correct anatomical description than "subdural." Dr. Symonds's suggestion that in one of our cases the blood came from a punctured vein has no application. All practitioners experienced in these matters will agree with us that there is no resemblance whatever between venous puncture blood and blood effusions such as the hæmorrhages we have described. We accept Dr. Symonds's evidence that a number of these hæmorrhages are due to aneurysm, but in our opinion the present state of our knowledge of the subject does not justify the assumption that all owe their origin to this condition. In our opinion the clinical histories of our cases and their response to treatment establish a strong argument in favour of a toxic origin. In our first case there were definite extra-meningeal signs of toxicity—viz., pleuro-pericardial friction and dilatation of the heart, which appear to us to be incompatible with a diagnosis of congenital aneurysm.

In the other two cases, cerebro-spinal fever was present in the area and the mode of commencement in both cases justified a preliminary diagnosis of meningococcal meningitis This disease is characterised by rapidity of onset in a large proportion of cases, perhaps particularly so during epidemic periods, and the commencement of these cases showed no material difference from the average experience. Both these cases were definitely toxic and showed a complete absence of localising signs other than meningeal We do not think a simple meningeal hæmorrhage would produce such clear clinical evidence of toxæmia, and while admitting the importance of the positive post-mortem findings in cases with somewhat similar signs and symptoms, we still hold our original view of our own cases

We are, Sir, yours faithfully,

A. G. BANKS
A. M. N. PRINGLE.

Ipswich, June 10th, 1926

## IMMUNISATION AGAINST MEASLES

*To the Editor of* THE LANCET.

SIR,—In a leading article in your issue of May 22nd you speak of the production of active immunity in measles as being still in the experimental stage I think an account may interest you of my experience when in charge of the Maison Maternelle at Châlons-sur-Marne last year. Apart from the obstetric wards this institution contains a pouponnière of four wards for 38 babies and a ward for children of 1–4 years. During July, 1925, a severe epidemic of measles attacked every child in the latter. Two of them had broncho-pneumonia and all were severely ill. All inter-communication with the pouponnière was stopped and the ward and its staff were isolated On August 8th, at 5 P.M., Marcel M., aged 9 months, in Ward No 1 (13 babies) was found to have a temperature of 38 3° C., with running eyes, coryza, and redness of throat. Until this moment he had had no symptoms of illness and the morning and evening temperature had been normal. He was at once isolated, and on August 10th had a typical measles rash. On the same day three other babies in Ward No 1 began to cough and sneeze On August 11th Antoinette M., aged 5 months, in Ward No. 2 (17 babies) had a temperature of 39° C, but no running of the nose. On August 11th all the babies, except Marcel M received a subcutaneous injection of 3 c.cm of *sérum de convalescent de rougeole* from the laboratory of the Claude Bernard Hospital, Paris No baby developed measles Antoinette A., of Ward No 2, had a slight rash on August 15th, which lasted 24 hours Her temperature was then normal, she had no coryza, and was not isolated The babies continued to gain in weight and to digest well. Their general condition remained excellent There was no local reaction at the site of the injection and no elevation of temperature.—I am, Sir, yours faithfully,

EDITH M. PYE

June 10th, 1926.

## CHRONIC DUODENAL AND GASTRIC ULCER

*To the Editor of* THE LANCET.

SIR,—May I reply very shortly to the letters appearing in your issue of May 22nd bearing upon the paper which appeared under my name on May 1st ? I am gratified by the kindness shown by Dr. Ryle and Mr. Adams in their criticism of what is acknowledged to be a very difficult subject. Mr. Adams (whose letter appears first) points out that according to my article I performed cholecystoduodenostomy where cholecystogastrostomy would have been the obvious thing to do. I omitted to record the fact that in both these cases a gastro-enterostomy had been performed without relief of symptoms. Mr. Adams also suggests that I do not believe in a rise of gastric acidity in gastric ulcer, and yet I claim to reduce it by cholecystogastrostomy. I wrote, "there is no characteristic wave at all," not that there is no wave. I ought to have emphasised the word "characteristic" and omitted the words "at all." I appreciate the well known and deservedly high place Dr. Ryle occupies in regard to analysis of gastric secretion, and I realise that his opinions are very valuable, but I am afraid I must differ from some of them. His chief complaint is that I do not value fractional analysis of gastric contents either before or after operation; more than this, he suggests that my experience of such analysis is very small. I do not think it necessary to add anything to what I said in my article with regard to my experience with the Reyfus tube, but as regards the rest I can assure Dr. Ryle the subject has been, and is being, adequately dealt with by the department of which I have control.

In answer to the very helpful letter from Mr. R. Leonard Ley in your last issue, I would say that American observers, using X rays, have shown that the stomach contents do not pass into the gall-bladder after the anastomosis, whereas by gastric analysis both they and we in Leeds have found that bile does pass freely into the stomach. Mr. Ley suggests that the performance of a modified Roux's operation whereby the divided proximal end of the jejunum is implanted into the stomach near the ulcer would ensure all the alkaline contents from the duodenum passing into the stomach I think this a brilliant suggestion. A somewhat similar operation was described by me (*British Journal of Surgery*, 1914) for traumatic rupture of the duodeno-jejunal junction, and no apparent physiological disturbance took place. I think, however, that the modified Roux's operation might prove formidable in the hands of many surgeons, whereas cholecystogastrostomy would prove easy. I am, Sir, yours faithfully,

L. R. BRAITHWAITE.

Leeds, June 3rd, 1926

## HOMOGENEOUS RADIATION

*To the Editor of* THE LANCET.

SIR,—The homogeneous radiation is generally accepted among radiologists. It seems daring, therefore, to question it. Nevertheless, on physical grounds I believe it to be wrong. My argument is as follows. First let the following axioms be accepted: (1) That unabsorbed radiation is therapeutically useless. (2) Therapeutic effect is directly proportional to absorption. (3) Absorption can only occur when the wave-length of the radiations is in resonance with those of the atoms on which it falls This was first put forward by Grotthus and is now generally accepted.

Consider the physics of absorption for a moment. Atoms consist of positively charged nuclei with negatively charged electrons revolving round them. These negative electrons can only revolve round the nucleus in certain definite orbits. If the right type of radiation is supplied absorption occurs. That is the electron is changed from one orbit to another or if the stimulus is sufficiently great is ejected altogether. But "if radiation of inadequate frequency is supplied it cannot change the particle from one orbit to another, it will be ineffective and achieve nothing. The particle takes no notice of any but a whole quantum of energy. The quanta are not all of the same size. To remove a particle from orbit 1 to orbit 2 requires a large quantum. To remove one from orbit 5 to orbit 6 quite a small quantum suffices" (Lodge: Atoms and Rays).

My conclusion is that the ideal radiation is one consisting of widely different wave-lengths. Such a radiation would be capable of being absorbed by electrons revolving in widely different orbits. A step in this direction has already been taken by the combined use of radium and X rays. I think that an even wider spectrum than this is desirable The homogeneous radiation with its sharply restricted wave-length must have a restricted absorption. It has, however, the merit of facilitating depth dosage.

I am, Sir, yours faithfully,

RICHARD E. SADLEIR, L.R.C.P.I., D.M.R.E.

Dublin, June 11th, 1926.

## SNOW-BLINDNESS.

*To the Editor of* The Lancet.

Sir,—I should like to comment shortly on one small part of Dr. W. Stewart Duke-Elder's very interesting article in your issue of June 12th. He says that the commonest form of solar photophthalmia "is that experienced after exposure to bright sunlight on a snow-field—usually called snow-blindness." In my experience, and that also of other explorers with whom I have associated, bright sun-glare on the snow is much less likely to produce symptoms of photophthalmia than a comparatively dull diffuse light. It is rarely that one finds a snow surface uniformly flat, like a tropic sea, for instance, and in sunlight irregularities, such as pressure ridges and lumps of ice, cast deep black shadows and stand out clearly, to be seen with little effort. The eye rapidly adapts itself to sun-glare, and rarely requires any special protection. On the other hand, in a diffuse light there are no shadows and details of the surface are hard to pick out, so much so that men on the march will stumble into large obstacles, of which till then they were quite unaware. Under these circumstances snow-blindness sets in rapidly—one hour without goggles may be sufficient to produce painful symptoms which develop within two or three hours of exposure. The condition can be prevented by means of properly designed snow goggles. I have used Crookes' B glass and Euphos 3 and found them effective, but to be sure of prevention side glare must also be cut off—best by a gauze of very fine mesh. The greater liability in diffuse light is, no doubt, largely due to the increased accommodative efforts used in an attempt to pick out detail from the dull whitish grey surroundings, devoid of colour or shadow, but the facts that side glare may cause the condition, and that goggles are effective to prevent it, show that this is by no means the only factor. Crookes and Euphos glass certainly give greater definition in bright sunshine, but this is not the case, or the improvement is very little, in diffuse light. In fact, most cases which I have seen have been due to men removing their goggles to get a clearer view. Fogging from deficient ventilation may, perhaps, have been the commonest cause for their removal, but had the loss of definition been at all considerable, the tendency would have been to clean and replace them at once. I have noticed also in other circumstances—e.g., when being driven across snow-covered tundra over a made trail, where there was no call for great accommodative effort, that a diffuse light was more irritating to the eyes than bright sunshine.

The injurious external stimuli acting upon the eyes in light diffused through cloud and reflected from snow must, therefore, be greater than those of sunlight reflected from the same surface. Since ultra-violet rays are responsible for the photophthalmic effects it would appear that there is a higher percentage in diffuse than in bright sunlight, but whether this is an established physical fact I do not know.

I can heartily endorse Dr. Duke-Elder's remarks as to the painful effects and the miserable condition produced in so far as snow-blindness is concerned. As standard treatment I used cocaine 3 per cent. followed by zinc sulphate ¼ per cent. in tabloid lamellæ. Adrenalin and pituitary extract gave striking and instantaneous relief for a short time, but their use was followed by an intense aching of the eye-balls and violent headache.

I am, Sir, yours faithfully,

A. H. Macklin,

Late Surgeon, Imperial Trans-Antarctic and
Dundee, June 13th. Shackleton-Rowett Expeditions.

## TITLE OF APOTHECARY.

*To the Editor of* The Lancet.

Sir,—In your issue of June 12th, under the proceedings of the General Medical Council, there is mention of an honours certificate being granted in obstetrics by the Society. Has not the time arrived when the ancient title of "apothecary" as applied to practitioners of medicine be eliminated? I presume that it would be a rarity, if indeed not a curiosity, to chance upon a modern holder of the licence of the Society fulfilling the duties and practice of men who were so ably described by Dickens, Thackeray, Trollope and other writers as an apothecary; while to the malicious, jealous, and unsuccessful it has often been used as a lever to the holder's detriment. Honours certificates may have their uses, but if the Society would endeavour to eliminate this word and modernise its title the certificate would be enhanced; the divorce from the druggist would be as decisive as that from barber and surgeon of the old days. I would suggest the letters should be L.S.P.S.—i.e., Licentiate of the Society of Physicians and Surgeons, thus avoiding conflict with existing examining bodies.

I am, Sir, yours faithfully,

June 15th, 1926. General Practitioner.

⁂ *The practical suggestion has been made before* with no result. There are real difficulties in changing the titles of Corporations which possess charters, are referred to in Acts of Parliaments, and hold property. There is also the view that to-day the world knows that apothecary is an old-world designation not defining the duties of its holder; members of the Cordwainers' Guild do other things than cordwain, and Yeomen of the Guard are no longer only yeomen. But our correspondent points to a situation which may, none the less, prejudice the holder of the L.M.S.S.A.—Ed. L.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

J. J. Cusack to be Surgeon Lieut.

### ROYAL NAVAL VOLUNTEER RESERVE.

The King has approved of the award of the Royal Naval Volunteer Reserve Officers' Decoration to Surg. Comdr. F. J. S. Heaney.

Col. W. P. Gwynn retires on retd. pay.

## ROYAL ARMY MEDICAL CORPS.

Lt.-Col. O. W. A. Elsner retires on retd. pay, and is granted the rank of Col.

The undermentioned to be Lt.-Cols.: Maj. and Bt. Lt.-Col. C. R. Sylvester Bradley, vice Lt.-*Col.* L. Wood (promoted), and Majs. S. E. Lewis, vice Lt.-Col. and Bt. Col. H. B. Fawcus (promoted), and G. A. Kempthorne, vice Lt.-Col. O. W. A. Elsner to retd. pay.

Capts. C. I. Hannigan and J. Grant-Johnston to be tempy. Capts. and temporarily relinquish the rank of Capt.

*General List.*—J. J. Seaton to be Temp. Lt. whilst empld. as a Dental Surg.

### RESERVE OF OFFICERS.

Capt. R. E. G. Phillips, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

### TERRITORIAL ARMY.

Maj. W. J. Harrison resigns his commn. and retains his rank, with permission to wear the prescribed uniform.

Lt. R. Jackson, late R.F.A., to be Lt.

## ROYAL AIR FORCE.

Flight Lt. B. F. Haythornthwaite is granted a permanent commission in this rank.

*Flying Officer* A. A. Townsend is promoted to the rank of Flight Lt.

## INDIAN MEDICAL SERVICE.

Lt. Col. H. M. Cruddas to be Col.

Lts. Som Dutt and Dawarka Prasad Bhargava to be Capts.

Shankar Parasharam Jashi, Sukumar Dutta Gupta, Kaikhushroo Maneckji Barucha, Monowar Khan Afridi, and Gurbaksh Singh Chawla to be tempy. Lts.

The King has approved the admission to the Ind. Med. Serv. of the following and to be Lts.: Bhagwant Singh Nat and Chiranji Lal Pasricha.

# Obituary.

## SIR HENRY MORRIS, BART., F.R.C.S.,

### LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

WE regret to announce the death on Monday last of the distinguished surgeon and professional leader Sir Henry Morris. He had been in bad health for some little *time, and an attack a few weeks ago* occurring at his advanced age indicated the probability that his life would not long be spared.

Henry Morris was born in 1844, the son of a medical man, William Morris, who practised in Sussex, and the grandson of a medical practitioner in North Wales. He received his preliminary education at Epsom College. He was one of the first 100 entrants at the new institution with the interests and advance of which

SIR HENRY MORRIS

his name will always be intimately associated; his date of entry was October, 1855, the head-master being the Rev. Dr. Thornton. From Epsom he proceeded to University College, London, and graduated in arts at a very early *age, later* joining the medical school at Guy's Hospital. He took the M.R.C.S. in 1866 and in 1873 the F.R.C.S., while he had already graduated in medicine at London University. He filled the resident posts at Guy's Hospital, and in 1870 was elected surgical registrar at Middlesex Hospital, thus commencing his long association with that institution. In the *following* year he was elected assistant surgeon to the hospital, on the staff at which time were, among others, Hulke and Douglas Powell (each like himself destined to preside over one of the great corporations), Lawson, Caley, and T. S. Cobbold, all names associated with various victories over disease. In his capacity both as teacher and surgeon he rapidly made a name for himself. He was extremely well read as well as clear, his undergraduate studies in moral philosophy and logic standing him in good stead, and under his peremptoriness of manner there lay a real desire to help the students in laying foundations of scientific knowledge along the path of surgery. He was elected to the full staff of the hospital in 1870 and served in that capacity for 27 years, until in 1906 he was made consulting surgeon.

In 1893 he commenced his first official connexion with the Royal College of Surgeons of England when he was elected on the Council, where for 21 years he served, and in 1906 was elected President in succession to Sir John Tweedy. Before election to the chair he had been for six years chairman of the Court of Examiners, *where his intimate knowledge of anatomy* both academic and in its application to surgical procedure, had a great influence. In 1898 he delivered the Hunterian lectures at the College, taking as his subject the origin and progress of renal surgery, a province of surgery in which he had already made a special mark. He was the first to perform the definite operation of nephro-lithotomy; the case was operated on in 1880 after diagnosis by Dr. Sidney Coupland, and the historic specimen, with the contemporary report, can be seen in the dean's room at the hospital. In 1903 he delivered the Bradshaw lecture of the College, taking as his subject cancer and its origin, and in that lecture he summarised a vast experience upon operable and inoperable malignant disease—again a province in which, alike by powers of diagnosis and manual ability, he had made for himself a prominent position. In 1904 he was appointed by the College to be its representative on the General Medical Council. This position he held till 1917, and during no less than 12 years was the treasurer of the Council. At the proceedings of the Council he was a *frequent and* strong debater, especially on educational questions, and more than occasionally his devotion to the interests of his College brought him into conflict with those whose policy was more directed to obtaining supervisory powers for the General Medical Council. He was particularly opposed to the compulsory registration of students by the G.M.C. and to the movement for disassociating the teaching of anatomy from the regular routine of a hospital medical school, a view which led him to give £1000 to the Middlesex Hospital to inaugurate an endowment fund for the medical school.

Morris was an accomplished writer, most of his contributions either as books, as chapters in symposia, or as scattered papers being devoted to one of three subjects—systematic anatomy and its surgical relations, renal and hepatic surgery, and the surgical treatment *of cancer.* His well-known System of Anatomy *made* its first appearance in the 'eighties and has now gone through five editions. Originally a sound text-book of human anatomy, it has been brought up to date and revised by a staff of authors representative both of English and American schools, and has become a comprehensive text-book, embracing a wide field of workers both here and in the *United States.* The Anatomy of the Joints of Man was published in 1878, and was recognised at once as forming a valuable addition to English text-books. It was poorly illustrated and the text was in some places redundant, but the accuracy of the descriptions and the skill and patience devoted to the explanation of the specimens noticed or depicted commanded immediate attention; there may not have been much originality of observation, but the minuteness of detail made of the book a valuable work of reference. He wrote the article on Injuries and Diseases of the Abdomen in Timothy Holmes's System of Surgery. He produced a treatise on *Diseases and* Injuries of the Genito-urinary Organs of the Male, which was followed up by a work on Diseases of the Kidneys and Ureter in which the ground covered by the Hunterian lectures of the College of Surgeons was thoroughly extended. A second edition of the work *appeared in 1901. The prominent feature* of all Morris's writings in this province of surgery was his quick *insight into practical methods, which* is well exemplified by the prompt employment that he made in his renal and hepatic work of the discovery of X rays. He was a contributor to Allbutt and Rolleston's System of Medicine and to Playfair Gynæcology, while he wrote the articles on Ren disease and diseases of the genito-urinary org Ashhurst's Encyclopædia of Surgery. His contri to the medical journals were frequent, and ther be found in our columns such instructive essays Cavendish lecture, which he delivered in 18 official lectures at the College of Surgeons, the

Oration at the Medical Society of London delivered in 1905, and the Hunterian Oration of 1909.

On the conclusion of his office as President of the Royal College of Surgeons in 1909, Morris was created a Baronet, but cessation of office at the College was almost at once followed by his election to the position of President of the Royal Society of Medicine, a post which he held for two years. His interest in the subject of cancer, manifested in so much of his work and writing, took practical shape when the Imperial Cancer Research Fund was inaugurated in his house; of this body he was vice-president and treasurer.

When the late Sir Constantine Holman, who had been a most active treasurer of Epsom College for 19 years, resigned in 1906, the Governors unanimously selected to succeed him Morris, who had been a member of the Council since 1888. From the time of his appointment he worked for the College with untiring zeal and energy; perhaps only those who were associated with him on the Council were able to realise fully the extent of the time and labour which he devoted to the duties, but his communications to The Lancet gave evidence of his deep interest in the Foundation. Besides acting as treasurer for 18 years, he was chairman of the Works Committee for almost as long a period, and in this capacity inaugurated or supervised many improvements at the College. Amongst these may be mentioned the erection of the Markham Skerritt Laboratories, the provision of improved heating and hot-water systems, enlargement of the infirmary, the provision of new workshops, gymnasium, and music block.

Morris was a great surgeon, and his leading position in the profession was obtained by industry, learning, enthusiasm for progress, and self-reliance. He was a man with strong opinions which opposition did not modify easily, as appeared from his conduct of business in many public capacities, and his views, whether of situations or of men, when arrived at were sure to be persistent, his individual estimate being led to play sometimes too prominent a part. To his high offices he brought a dignified presence, and also a fine ideal of work, but he had not quite the success as an orator which he coveted, his speeches being often too long and too detailed to carry the audience with him. But though such small criticisms were common in regard to him, Morris commanded the real respect of the profession in a universal way as one who had added to our store of learning and accomplishment, one who was untiring in his efforts to advance the national health, and one who was devoted to the best interests of his calling.

## FREDERICK MOTT, K.B.E., M.D., F.R.C.P. LOND., LL.D. EDIN., F.R.S.,

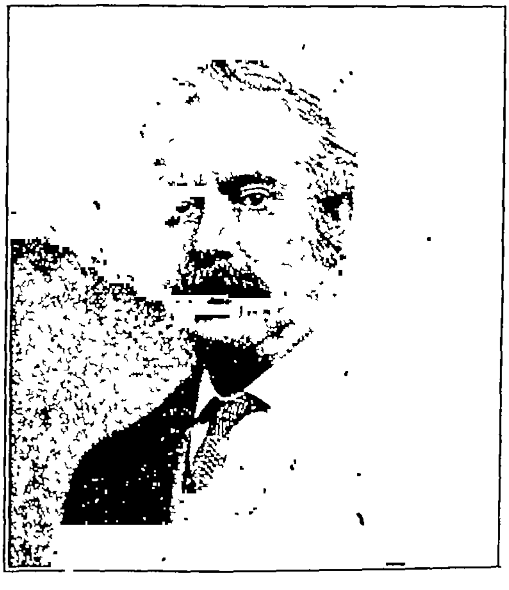
DIRECTOR, PATHOLOGICAL LABORATORY, MAUDSLEY HOSPITAL; CONSULTING PHYSICIAN TO CHARING CROSS HOSPITAL.

A brief estimate of the work of Sir Frederick Mott, which appeared in these columns last week, announced to the medical public the loss which has been sustained by his death.

Frederick Walker Mott was the son of Mr. Henry Mott, of Brighton, where he was born in 1853, and received his early education. He entered the medical school of University College, where he graduated as M.B. with first class honours in 1881, being University scholar and gold medallist in forensic medicine. After holding the usual appointments he went to Vienna, where he studied pathology and mixed largely with foreign post-graduate workers, thus laying the foundation of his international position. He proceeded to the M.D. in 1886, taking also the M.R.C.P., and in 1884 was appointed lecturer on anatomy and physiology at the Charing Cross Medical School —the two subjects were covered by one lecturer very frequently 40 years ago. This appointment he obtained on the direct suggestion of Burdon-Sanderson, who wrote disclaiming any knowledge of Mott save that derived from his work, certain portions of which had come before him and had much impressed him. In 1890 he was elected assistant physician to the hospital, with special charge of diseases of children, while he supervised also the electrical department. He became full physician three years later, and lectured in the school first on general pathology and then on neurology. For a time he was chairman of the school committee, and in all these important connexions with the school and hospital he has left behind him a memory for unceasing interest in the institution and in the welfare of the students, for devotion to work, and for great personal kindness.

Mott's labours and performances as a neurologist were so important and so far-reaching that a summary of them is not an easy task. The work of many men who have enriched our scientific knowledge may be often dealt with as a series of more or less independent contributions, the value of each being unrelated in the historical sense to its predecessor. To study the influence of Sir Frederick Mott on medical and scientific thought is in a very special sense to study historically the development of his life's work. The work of Mott, beginning with broad fundamental studies of the physiology of the nervous system, progresses in a logical order to the examination of the structure on which physiological activity depends, next to the pathological disorders of structure, later to the concomitant evidences of functional disorder attending it, and finally to considerations of the psychological implications of pathological disturbances in the nervous mechanisms.

Mott was first drawn to the study of the nervous system in the years succeeding the fundamental work of Hitzig, Munk, and Ferrier, at a time when there was still much to be done by broader and freer experimental methods than those that are possible in the present day. His work in conjunction with Schäfer on cerebral localisation added much to our knowledge of the motor functions of the cerebrum. Later followed much work on the sensory functions of the cortex and his well-known experiments with Sherrington on the apæsthetic limb. Other work followed dealing with the functional activities of the spinal cord. From these physiological experiments Mott turned his attention to the histology of the nervous system. He demonstrated the thalamic connexions of the fillet and did much to formulate the anatomy of the spinal encephalic systems.



[Elliott & Fry.

Sir Frederick Mott.

On his appointment as pathologist to the Central Laboratory of the London County Asylums, Mott began to interest himself more especially in the pathology of the nervous system in connexion with the psychoses. With characteristic directness he dealt first with the one form of insanity which in those days was recognised as undoubtedly associated with gross changes of the central nervous system Krafft-Ebbing had already proclaimed the syphilitic origin of general paralysis, but his views were only accepted by a minority of psychiatrists in this country, and, as Mott pointed out in his epoch making paper on the Ætiology of General Paralysis, the word syphilis did not even find a place in the index of Bevan Lewis's standard text book on psychiatry By the analyses of a vast amount of clinical and anatomical evidence, nearly all of which was collected and prepared in his laboratory, the syphilitic origin of general paralysis was once and for all irrefutably demonstrated in days before the Wassermann reaction had made the path of investigation comparatively easy Mott's great work on the relation of syphilis to insanity and tabes was published in the first volume of the *Archives of Neurology*, which he founded and continued to edit In the successive volumes of the *Archives* appeared numerous studies on the various aspects of the pathology of the nervous system in the psychoses, all tending to establish more and more firmly the correlation of structural change in the nervous system with disorders of conduct.

The responsibilities of his office led him at the same time to undertake investigations which had a far reaching influence on the treatment of the insane The hygienic condition of the mental hospitals was 30 years ago very far behind the standard which obtains to-day, and Mott threw himself whole heartedly into the work of reform He had in the early days to encounter great obstacles and to overcome much ill informed opposition, but it is from his inquiries into the bacteriology of hospital dysentery and tuberculosis, and by the reforms which he advocated, that an enormous reduction of the mortality from these diseases was achieved in the mental hospitals. His influence also made itself felt in countless reforms of the dietary and general hygiene of mental patients and throughout his whole career he was animated by a very intense sympathy and human interest in the insane

At the beginning of the present century Mott had already accomplished a vast amount of work on the investigation of the nervous system by physiological and anatomical methods, but he was quick to perceive their limitations and he became convinced that the future of pathology was to be to a great extent in the hands of the biochemist and physicist Although he recognised that these more specialised investigations required an entirely new orientation he attacked the problems with conspicuous courage The cerebrospinal fluid as the supposed nutrient medium of the central nervous system first engaged his attention, and though he later on abandoned many of the views that he advanced together with Halliburton on the source of choline, his Croonian lectures still remain a record of the first attempt to seek for products of nervous disintegration in the living body Later he followed up the same line of inquiry with microchemical methods.

The importance of the study of the autonomic nervous system and endocrine organs to psychiatry engrossed him later He perceived that the mechanisms of the affective states were likely to be of supreme importance in the understanding of disorders of conduct He proceeded to concentrate his attention on the pathological histology of the secretory structures and the vegetative nervous system His studies on the endocrine organs and the sympathetic system in dementia præcox are of fundamental importance It is in a great measure due to this work that whatever view we may take of the origin of the psychical symptomatology of dementia præcox it is possible to trace much of the disordered conduct to a definite and widely spread bodily change In the group of psychoses due to endocrine disorders and many of the types of manic-depressive insanity he was again able to point to a generalised bodily disturbance

Mott believed that the study of the pathological anatomy of dementia præcox afforded some evidence of its congenital origin, and in an attempt to further this view he devoted much attention to the study of heredity in the insane. From an analysis of the vast material that he collected from the London mental hospitals he formulated the "Law of Anticipation" in insane stock, according to which the psychotic factor appears earlier in each succeeding generation and thus unaided nature tends to eliminate the tainted progeny He pointed out that this factor was of greater importance in the elimination of hereditary psychoses than anything that could be achieved by segregation or sterilisation, since the period of greatest fertility precedes the development of those symptoms which would bring the individual under control

During the war Mott acted as consultant to a neurological clearing hospital, and for a time his attention was to some extent diverted from the study of the psychoses to that of the neuroses. He found that in the vast majority of cases of war-time neurosis there was a history of previous nervous instability, and he taught that the strain of war only became an effective cause of neurosis in those patients who already possessed a constitutionally neuropathic disposition In other words, he considered that just as his investigations of the psychoses had demonstrated pathological changes in the nervous and somatic mechanisms, so a similar disturbance should be demonstrable in the neurotic, and this disturbance he suspected to be in the mechanisms subserving the organic response to emotion. During this period he devoted much time and thought to the adjustment of organic pathology to the facts of pathological psychology He was frankly sceptical of the results claimed for the methods of psycho analysis, and in his psychological investigations he adopted a modified behaviouristic attitude He steadfastly declined to commit himself to any metaphysical theories of the relation of mind and body He had early revolted from the crude materialism of Victorian physiology, and beyond this point as a scientific worker he refused to go

No appreciation of the influence of Mott on medical science would be complete without some reference to the part that he took in the foundation of the Maudsley Hospital. He regarded the formation of a school for the teaching of psychiatry and the furtherance of research work as one of the great achievements of his life. To this end he induced the London County Council to establish well-equipped clinical laboratories at each of the mental hospitals which are conducted in close connexion with, and to some extent under the supervision of, the Central Laboratory at the Maudsley Hospital It is mainly due to his efforts that a Diploma in Psychological Medicine has been established by the London colleges and many of the universities, and he acted as honorary director of the courses held for this degree at the Maudsley Hospital, where to the last he lectured on pathology and pursued his research work in the laboratory

The great work accomplished by Mott for scientific psychiatry was not alone dependent on the value of his monumental researches His life was characterised by an innate modesty and simplicity of character which made him accessible to all those who wished to consult him, and there are few workers in the field of psychiatry who have not at some time personally benefited by his common sense and scientific acumen His kindliness endeared him to all, and those who had the privilege of working with him will remember him both as a great master and a great friend

His publications were numerous and a very large proportion of them have appeared in these columns, where will be found the Croonian lectures delivered before the Royal College of Physicians of Lond the subject being the degeneration of the neurone, the Lettsomian lectures delivered before the Medical Society of London on the effects of high explosives upon the central nervous system, and many contributions upon various neurological conditions. He wrote on these in the Encyclopædia Britannica, and contributed frequently to the *Transactions* of the Royal Society and to *Brain*, which he edited, as well as contributing largely to the *Archives of Neurology and Psychiatry*, which he founded. The material for all this work was obtained from his hospital wards and from his opportunities as pathologist to the London County Asylums, so that all his written work was informed throughout by his personal experience. Elected F.R.S. in 1896, he was also Fothergill Gold Medallist, Moxon Gold Medallist of the Royal College of Physicians, and a Fellow of University College, London, and had been Fullerian Professor of the Royal Institute. He was created K.B.E. in 1919, held a Roumanian Order, and was a corresponding member of many foreign societies.

In private life his widely acknowledged distinction made no difference to his unassuming manner. He was a kindly friend and a generous host, a quietly amusing talker, and devoted to music. He married in 1885, Georgiana, daughter of the late Mr. G. T. Soley, by whom he had four daughters, to whom we extend all sympathy. A largely attended memorial service was held at St. Martin's Church on Wednesday last.

---

## ARTHUR CONYERS INMAN, M.B., B.CH. OXF.

THE medical profession has suffered a severe loss by the untimely death of Dr. A. C. Inman, for he was a pathologist who touched the practice of clinical medicine at many points.

Arthur Conyers Inman was born in Kensington in 1879, the son of the Rev. H. T. Inman. He was educated at Haileybury and St. Edward's School and Wadham College, Oxford, taking his degree in natural science in 1900, then going on to St. Thomas's Hospital, London, for the clinical part of his training. After qualifying in 1904 and holding resident appointments at St. Thomas's and the Brompton Consumption Hospitals he became interested in pathology and worked in Sir Almroth Wright's laboratory at St. Mary's, at the Pasteur Institute in Paris under Metchnikoff, and as voluntary assistant in the pathological department at Dresden; it was only after obtaining the broad view that comes from seeing methods and following other people's investigations on a large scale that he returned to London to become superintendent of the pathological laboratories at the Brompton Hospital. Here he became counsellor and friend to successive generations of house staff and resident officers, causing them to look into the pathological basis of their clinical work and receiving himself stimulus to successive investigations. His early association with Dr. M. S. Paterson was especially fruitful. Inman devoted much time to estimating the exact value in the diagnosis of tubercle of such helps as the opsonic index, complement fixation, the Arneth index, and the sedimentation test, but he always made it clear that the interpretation of these results rested with the clinician who could take into consideration all the factors in diagnosis. In all his work Inman gave the closest attention to detail, and it was characteristic of him that he would undertake nothing unless he could do it thoroughly. A few successful cases in the early stages of experiment never misled him to publish them as results. While, therefore, his contributions to medical literature may be comparatively few they are at least sound. His work, as that of any honest worker, often led him down a blind alley; he labelled these alleys so that no time need be wasted by others in traversing them. One of these blind alleys was an attempt to find a specific treatment against secondary infections in cases of advanced tuberculosis. Inman concluded from his work that there was no hope of a successful issue in this direction. It was Inman who did what no clinician had succeeded in doing; he suggested a simple clinical classification of pulmonary tuberculosis, and many practitioners have reason to bless him for the precision of the three groups: resting febrile, resting afebrile, and ambulant afebrile cases.

During the war Inman became honorary captain in the R.A.M.C., and was posted as specialist bacteriologist to various centres. At one or other of the research laboratories attached to the Expeditionary Force in France he was able to make a study of the biology of infected wounds and especially of the tryptic properties of pus which led to important deductions in the choice of antiseptics and the mechanism of wound drainage. Later on, at the Mont Dore Military Hospital at Bournemouth, he pointed out the high percentage of dysentery convalescents who were returning to this country carrying entamœba cysts and showed the need for careful protozoological examination of every case of dysentery coming under investigation. During this time he was engaged with Prof. G. Dreyer and others in a study of the agglutination curve in inoculated persons which resulted in a singularly valuable clue to the diagnosis of typhoid and paratyphoid fevers, the results being interesting for the high degree of mathematical accuracy. Much of this work was embodied in reports presented to the Medical Research Council.

DR. A. C. INMAN.

Something should be said of Inman's powers of organisation, a quality much valued by those who worked with him. His orderly mind would make a success of any meeting, no doubt because he was in the habit of giving the same thought and attention to detail in the arrangement of a conference as he did to making up a dinner party—and he was a charming host. He was a good linguist and always followed the foreign literature on the subjects he was studying, but not to the exclusion of the work done at home with which he was fully acquainted. Hence he was an ideal colleague in literary work, and the text-book on pulmonary consumption published in collaboration with the late Dr. A. C. Latham owed much to Inman's careful preparation which formed its groundwork.

Dr. Inman was twice married; in 1909 to Dorothy, only child of Dr. F. J. Wethered, and in 1919 to Mlle. Colette Frey of Paris. Travel came first among his recreations, but he was also a keen cricketer and a lover of good music. His death, which occurred in a nursing home at Rouen, was due to the disease which he spent his life in investigating, accelerated at the last by glycosuria.

## GERHARD HOTZ, M.D. BASLE AND WÜRZBURG,

### PROFESSOR OF SURGERY AND DIRECTOR OF THE SURGICAL CLINIC IN THE UNIVERSITY OF BASLE.

THE death of Prof. Hotz is a severe loss to surgical teaching and removes a figure loved and honoured far beyond his native city. Gerhard Hotz was born in Basle on June 8th, 1880, the son of Dr. Rudolf Hotz-Linder, teacher in the High School. He took the Federal qualification in 1905, became surgical assistant in the Bürgerspital under Prof. Enderlen, and followed his master to Würzburg in 1907, where he gained a thorough introduction to modern surgical method and began to acquire organising ability. After taking his degree in Würzburg in 1909 he received the title of professor in 1911 and shortly afterwards refused an invitation to Chicago in order to become surgeon in charge of the Deaconess House in Freiburg. It was while he was there that war broke out and Hotz received permission from the Swiss Army Medical Department to remain in Freiburg, where he took over a large part of the systematic teaching and became responsible for a war hospital which, with its adnexa, gave him at times 600 beds under his personal care. At this period he made intensive studies of gunshot nervous injuries with Dr. Hoche, director of the Nerve Clinic, and with an extensive private surgical practice lived an extraordinarily full life complicated by shortage of food and harassed by the activities of enemy aeroplanes which destroyed the Anatomical Institute close to his hospital.

PROF. HOTZ.

In 1918 Hotz returned to Basle to occupy the surgical chair left vacant by the departure of de Quervain for Berne. The position of a professor of surgery in a continental clinic is something different from what we know in this country. He is the absolute head of a surgical establishment which includes laboratories, X ray and electro-therapeutic equipment, and through his hands pass all the important and exceptional surgery of the district. It thus becomes easy for him to organise through his assistants clinical demonstrations on a grand scale and to place the teaching of surgery on a systematic basis. Less fortunate surgeons visiting his clinic found Hotz teaching elementary students by means of lecture-demonstrations in the course of which patients, museum specimens, skiagrams, and diagrams illustrating anatomy, physiology, and pathology were shown. The pressure of one button brought up a fresh blackboard or a new drawing, another excluded daylight in a few seconds, every possible dissection was ready to hand, and his voice was never drowned by the roar of traffic. His writings include useful work on abdominal emergencies and on blood transfusion, but his teaching for the most part has no record except in the careers of his assistants and pupils.

In physique Hotz was a slight, alert man of medium height with quiet incisive manner and unfailing sympathy both for patients and students. A visit paid to Basle three years ago by the heads of surgical units in this country gave him an opportunity for intimacy which was availed of then and since by both parties. One of the visiting surgeons writes of him as a man who exerted a good influence which could be seen and felt in all his surroundings. "Hotz was," he adds, "more than a surgeon, he was a philosopher." He played a prominent part in the life of his native city and would have served on municipal and federal councils had his strength permitted, but his work was carried on under the constant shadow of illness. Just after being appointed to the chair of surgery he had a gastric perforation which required immediate operation, and once again during his term of office he came under the surgeon's knife. On this account he forswore all enjoyments and engagements outside the work of the clinic and practised a rigid abstemiousness. His premature death at the age of 46 was due to the perforation for the third time of a gastric ulcer.

Prof. Hotz was happily married to Frl. Orsolina Fanconi, of Samaden, and surgeons in many lands join in sympathy with his widow and six children.

# Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council held on June 10th, Sir John Bland-Sutton, President, being in the chair, diplomas of Fellow were conferred upon 27 men and 2 women who were successful at the recent examination held from May 20th to June 2nd Of the 110 candidates who presented themselves, 34 were approved and 76 were rejected. Five candidates—G. F. G. Batchelor (Guy's), B. H. Boggon (St. Thomas's), G. F. Gibberd (Guy's), R. W. Jones (Liverpool), and John Lewin (Guy's)—are not yet of age to receive the diploma. The following are the names and medical schools of the candidates upon whom the diploma was conferred :—

Geraldine M. Barry, Royal Free; H. Barbash, Cambridge and St. Bart.'s; R. Brooke, Guy's; B. H. Burns, Cambridge and St. George's; D. A. Davies, St. Thomas's; J. L. Diggle, Melbourne and Guy's; H. C. Edwards, King's Coll.; K. H. Hadley, Melbourne and Guy's; L. M. Ingle, Cambridge and London; Erna Henrietta Jebens, St. Mary's; S. R. Joglekar, Univ. Coll. and Guy's; R. P. S. Kelman, Otago; G. King, London; F. Langford, Bristol and Guy's; F. Louis, Univ. Coll.; C. A Lupton, Cambridge and St. Thomas's; A. L. McGregor, Edinburgh; J. D. McLaggan, Aberdeen and St. Bart.'s; D. P. Marks, St. Thomas's; D. S. Middleton, Edinburgh; D. W. G. Murray, Toronto and London; F. C. Ormerod, Manchester and Westminster; G. G. Penman, St. Thomas's; F. W. M. Pratt, St. George's; J. N. Sankey, Birmingham; J. J. Savage, Oxford and St. Bart.'s; W. R. Spurrell, Guy's; H. J. Taggart, Belfast and London; and C. H. Thomas, St. Bart.'s.

The diploma of Member was conferred upon A. H. F. Cole, Durham University, and L. Dass, Punjab and Middlesex Hospital, who have now complied with the by-laws of the College.

The following gentlemen were elected examiners for the ensuing collegiate year:—

*Board of Examiners for the Fellowship.*—Anatomy: William Wright (London) Frederick G. Parsons (St. Thomas's), W. E. Le Gros Clark (St. Bart.'s), and Cecil P. G. Wakeley (King's Coll.). Physiology: David H. de Souza (King's Coll.), F. Roberts (Cambridge), J. B. Leathes (Sheffield), and Herbert E. Roaf (London Hosp.).

*Conjoint Board.*—Biology: T. W. Shore (St. Bart.'s) and James P. Hill (Univ. Coll.). Anatomy: Henry A. Harris (Univ. Coll.), Oscar E. Hillman (Middlesex), and John B. Hume (St. Bart.'s). Physiology: C. A. Lovatt Evans (St. Bart.'s) and G. A. Buckmaster (Bristol). Midwifery: Eardley Holland (London), Donald W. Roy (St. George's), H. Beckwith Whitehouse (Birmingham), and Clifford White (Univ. Coll.).

Sir Cuthbert Wallace and Prof. William Wright were appointed to conduct the examination in pathology which candidates will be required to pass under the revised regulations of the Conjoint Board.

UNIVERSITY OF LONDON.—The following students have passed in one of the two groups of subjects for the Third (M.B., B.S.) Examination for medical degrees :—

*Group I.*—Florence A. Adam, London Sch. of Med. for Women; Shriharsh Chintaman Bakhle, Guy's Hosp.; Kathleen Blake, King's Coll. Hosp.; James W. Bottoms, London Hosp.; Edith D. Bowie, King's Coll. Hosp.; Alison M. Clark, London Sch. of Med. for Women and St. Mary's Hosp.; Frederick J. T. Foenander, Middlesex Hosp.; Dora J. Fox, London Hosp.; Elsa C. A. Fristedt, London Sch. of Med. for Women; Bernard M. C. Gilsenan, St. Bart.'s Hosp.; Minnie Gosden, London Hosp.; Charles H. Hampshire, Univ. Coll. Hosp.; Catherine M. Hext, London Hosp.; David P. Holmes, Westminster Hosp.; Morfydd R. Jones, London Sch. of Med. for Women; Michael C. Lavin, London Hosp.; Solomon Levy, Middlesex Hosp.; Norman W. MacKeith, Guy's Hosp.; Evelyn T. D. Maclagen, St. Mary's Hosp.; Evelyn M. Pakeman, Londn Sch. of Med. for Women; William E. Parry, London Hosp.; George E. G. Peirce, St. Mary's Hosp.; Agnes N. Ramsbotham, London Sch. of Med. for Women; Jacobus W. Schabort, Guy's Hosp.; Eustace F. Stead, London Hosp.; Edith A. Straker, London Sch. of Med. for Women; Sylvia Sworn, Univ. Coll. Hosp.; Frederick W. Ta'Bois, London Hosp.; Edith M. Webb, London Sch. of Med. for Women; and Herbert F. Wilson, London Hosp.

*Group II.*—James R. Beagley and Wynn R. W. Bonner-Morgan, St. Bart.'s Hosp.; Rose A. Carter and Evangeline A. Clark, London Sch. of Med. for Women; Arthur C. Counsell, Middlesex Hosp.; Brian R. Crossley, Univ. Coll. Hosp.; Muriel Davies, Westminster Hosp.; John C. G. Dickinson, Guy's Hosp.; John D. Durance, St. Mary's Hosp.; Donald C. Fairbairn, Oswald F. Farndon, and Maurice Fishman, St. Bart.'s Hosp.; Stanley C. Gawne, University of Liverpool; Sydney A. Grant, London Hosp.; James I. Griffiths, Univ. Coll. Hosp.; Frederick D. M. Hocking, Middlesex Hosp.; Douglas S. Huskisson and Frederick H. K. Knight, Guy's Hosp.; Elsie Lyon and Margaret B. MacDonald, Charing Cross Hosp.; Lewis J. McGregor, St. Thomas's Hosp.; Ian McPherson, Middlesex Hosp.; Mary A. Marshall, St. Mary's Hosp.; George A. Martin, Guy's Hosp.; Grace E. Mizen, Charing Cross Hosp.; George A. H. Norman, Westminster Hosp.; Bethan Phillips, Univ. Coll. Hosp.; Howel J. Powell, St. Mary's Hosp.; Muriel A. Pugh, Charing Cross Hosp.; James E. C. Rouse, St. George's Hosp.; Douglas J. L. Routh, Univ. Coll. Hosp.; Lewis H. Savin, King's Coll. Hosp.; Sidney T. Seccombe, St. Thomas's Hosp.; William D. Sheldrake, Guy's Hosp.; Mary Stirk, University of Manchester; Stephen V. Strong, Guy's Hosp.; Oxburgh G. Tippett, St. Thomas's Hosp.; John R. Tree, Middlesex Hosp.; and Elizabeth M. Whishaw and James T. Wybourn, St. Mary's Hosp.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful :—

FINAL EXAMINATION FOR DEGREES OF M.B., CH.B.

*Part II., with Second-class Honours.*—Stanley P. Taylor (distinction in Pathology).

*Pass.*—Richard E. Satchwell.

*Pass (completing Examination).*—John F. O. Bodman, Muriel E. Drew, Frank J. Farr, Mildred B. Harvey, and Arthur A. B. Vincent.

*In Group I. (completing Examination).*—Cecily France-Hayhurst.

*In Group I. only.*—Ernest May and Ernest S. Rogers.

TUBERCULOSIS SOCIETY.—A meeting of this society will be held on June 26th, at 3.30 P.M., at the Queen's Hospital, Sidcup. A demonstration of the ultra-violet ray department of this hospital, followed by lantern demonstration of radiograms, has been arranged.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On June 24th, at 2.30 P.M., Mr. H. Tyrrell Gray will give a special clinical demonstration in surgery at the Great Ormond-street Hospital, and on the 25th Mr. Goulden at the Royal London Ophthalmic Hospital will give a clinical demonstration in ophthalmology at 12.45 P.M. Both demonstrations are open to the medical profession without fee. The following courses will be held during July: At the N.E. London Post-Graduate College (Prince of Wales's General Hospital), Tottenham, a course in medicine, surgery, and the specialties, lasting from July 19th to 31st and occupying all day. From July 5th to the 17th the National Hospital for Diseases of the Heart will give an all-day course in cardiology, and between the same dates there will be a course in dermatology at the Hospital for Diseases of the Skin, Blackfriars, taking place each afternoon. The West End Hospital for Diseases of the Skin will begin a month's course on July 19th, consisting of lectures and clinical demonstrations upon selected cases each afternoon at 5 P.M., and finishing on August 14th. From July 12th to the 24th the Royal Eye Hospital will give a series of demonstrations on the treatment of diseases of the eye, taking place every afternoon at 3 P.M. Copies of all syllabuses, of the General Course Programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship of Medicine, at 1, Wimpole-street, London, W. 1.

KING'S COLLEGE HOSPITAL.—It is announced that the reduced expenditure of 1925 will allow of the re-opening of one of the closed wards.

RESEARCH DEFENCE SOCIETY.—The annual general meeting will be held at the House of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Friday, June 25th, at 8 o'clock, when the chair will be taken by Lord Lamington, and Dr. J. A. Murray will give an address on the Experimental Attack on Cancer.

WELSH NATIONAL SCHOOL OF MEDICINE.—Mr. A. W. Sheen, professor of surgery, has been appointed dean of the faculty of medicine on the retirement of Prof. T. Graham Brown from this office. Sir Ewen Maclean, professor of obstetrics and gynæcology, has been elected President of the British Medical Association for 1928, when the annual meeting will be held at Cardiff.

MEDICAL GOLFING SOCIETY.—The 29th annual summer meeting was held at Wentworth on June 10th. The scratch results were as follows: THE LANCET Challenge Cup, H. D. Gillies. Milsom Rees Challenge Cup, A. H. Gosse and F. A. Juler. Handicap results were: Class I., A. S. Gordon and A Galletly tied at 1 down. Class II., C. Scott Gillett and F. A. Juler tied at 2 down. Foursomes were won by T. P. Kolesar and W. R. Bristow.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—Prof. Hugh Cabot, professor of surgery in the University of Michigan, who has been taking charge for a fortnight of the teaching of surgery in Sir Holburt Waring's Clinic, was admitted on June 9th as an honorary perpetual student of St. Bartholomew's Medical College, an honour conferred only once before, when Prof. Harvey Cushing had charge of the teaching of surgery in Prof. Gask's Clinic in 1922.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: MATERNITY AND CHILD WELFARE GROUP.—The annual meeting will be held on July 6th at the Caxton Hall, Westminster, at 5.30 P.M. Mr. George Waugh will introduce a discussion on tonsils and adenoids in a paper on the Growing Significance of Diseased Tonsils and Adenoids: an Historical Survey, and will be followed by Dr. R. C. Clarke who will discuss the Ætiology of Enlarged Tonsils and Adenoids and the Causes of Failure of Operation. Dr. Harold Waller will then speak on the Early Symptoms and Signs of Ill-health Associated with Diseased Tonsils and Adenoids.

A dinner open to all medical practitioners attending this meeting will be held at the Florence Restaurant, 56, Rupert-street, London, W., at 7.30 P.M., on the same day (tickets 4*s.* each). Those who wish to attend this dinner are requested to communicate before June 30th with the hon. secretary, Dr. Margaret Emslie, at 1, Upper Montague-street, Russell-square, London, W.C. 1.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the monthly meeting of the Faculty held on June 7th the following were admitted as Honorary Fellows of Faculty :—Sir Hector Clare Cameron, C.B.E., M.D., LL.D., and George Stevenson Middleton, M.A., M.D., LL.D. The following were admitted after examination as Fellows of Faculty :—Jethalal Mansingbhai Damany, M.B., B.S., Bombay; Geoffrey Balmanno Fleming, M.B.E., M.D., B.A., Glasgow; Thomas Jackson, L.R.C.P. Edin., L.D.S., Cheltenham; Robert Aim Lennie, M.B., Ch.B., Glasgow; John King Rennie, M.C., B.Sc., M.B., Ch.B., Glasgow; Charles Rudd, M.B., Ch.B., D.O.M.S., Birmingham; William Smith Syme, Junr., M.B., Ch.B., Glasgow; James Nisbet Tennent, B.Sc., M.B., Ch.B., D.O.M.S., Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At a meeting of the College held on June 8th the following motion came up for determination :—

That William Lloyd, a Licentiate of the College, registered as of 58, Brook-street, Grosvenor-square, London, W. 1, having acted in an unbecoming and unprofessional manner, in respect that he, being a registered medical practitioner: (*a*) Sought to obtain patients and to promote his own professional advantage by means of an article published in the *Daily Mail* of June 5th, 1925, entitled: "Hay Fever—New Treatment—Specialist's Report—Patients Cured"; which was based upon materials supplied by him; and (*b*) sought to obtain as patients certain persons who, after reading the article, had written to the *Daily Mail* for his address, and whose letters were forwarded to him by the *Daily Mail*, and to whom he wrote inviting appointments to be made for treatment, although they had not themselves communicated with him—be censured.

The motion was carried.

The College voted a donation of 100 guineas to the Scottish National Memorial to Queen Alexandra. The College voted a sum of 100 guineas to the Extension Fund of the Incorporated Edinburgh Dental Hospital and School.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

ON Monday, June 14th, the Reading University Bill was read a second time.

### *Vaccination Bill.*

On Tuesday, June 15th, Mr. GROVES presented a Bill to amend the law relating to compulsory vaccination, which was read a first time.

## HOUSE OF LORDS.

### TUESDAY, JUNE 15TH.

### MIDWIVES AND MATERNITY HOMES BILL.

The Midwives and Maternity Homes Bill was considered on Report.

Part 1 of the Bill amends the Midwives Acts, 1902 and 1918. Clause 1 provides that if any person, being either a male person or a woman not certified under the Bill, attends a woman in childbirth otherwise than under the direction and personal supervision of a duly qualified medical practitioner, that person shall, unless he or she satisfies the court that the attention was given in a case of sudden or urgent necessity, be liable on summary conviction to a fine not exceeding £10.

During the Committee stage of the Bill in the House of Lords the clause was amended by the addition of the following proviso: "Provided that the provisions of this subsection shall not apply in the case of a person who, while undergoing training with a view to becoming a duly qualified medical practitioner or a certified midwife, attends a woman in childbirth as part of a course in practical instruction in midwifery."

The Marquess of SALISBURY, Lord Privy Seal, now moved to amend this proviso, so as to make it read, "a course in practical instruction in midwifery recognised by the General Medical Council or by the Central Midwives Board." He said that during the discussion of the amendment in Committee, Lord Knutsford expressed the view that the exemption for medical students and pupil midwives was not sufficiently safeguarded. On his suggestion, the Government now proposed that the exemption should only apply to students who were in training with a view to becoming duly qualified medical practitioners or pupil midwives, anxious to become certified midwives, if the course of practical instruction at which they were working was recognised by the General Medical Council or the Central Midwives Board.

The amendment was agreed to.

Clause 11 of Part 3, which is the interpretation clause, provides that a local supervising authority may grant exemption from the operation of Part 2 of the Act, which provides for the registration of maternity homes, of any hospital or other premises for the conduct of which a duly qualified medical practitioner resident therein is responsible, or any hospital or institution not carried on for profit, and not mainly used as a maternity home. It also provides that any person aggrieved by the refusal of a local supervising authority to grant exemption under Part 2 in respect of any hospital, premises, or institution, or by the withdrawal of any such exemption previously granted by the authority, may appeal against the refusal or withdrawal to the Minister of Health, who, after considering the matter, shall give such directions as he thinks proper and the authority shall comply with any directions so given.

Lord MUIR MACKENZIE moved to transfer these provisions from Part 3 to Part 2 of the Bill. He explained that his amendment did not touch the substance of the measure. He had been in communication with the Ministry of Health, who thought that the provisions referred to ought to be transferred to Part 2.

The Marquess of SALISBURY accepted the amendment, which was agreed to.

The Report stage of the Bill was concluded.

## HOUSE OF COMMONS.

### TUESDAY, JUNE 8TH.

### PROTECTIVE DUTIES ON SCIENTIFIC INSTRUMENTS.

The House went into Committee on the Finance Bill, Captain FITZROY, Deputy Chairman of Committees, in the chair.

On Clause 10 (Continuation and Amendment of Part I. of Safeguarding of Industries Act, 1921), which deals with the safeguarding of key industries,

Sir R. THOMAS moved to leave out Subsection (1), which renews the duties under Part I. of the Safeguarding of Industries Act, 1921, for a further period of ten years from August 19th, 1926. He said that he had always opposed the principle of safeguarding key industries and he was as convinced to-day as he was when the Bill was first introduced that it was a pernicious one and had raised prices. It was unfair that the present Government should attempt to bind future Governments for such a long period as ten years.

Mr. DALTON said that this clause in the Finance Bill was a relic of war psychology and of conditions which had now very largely passed away. Even in 1921 it was thought that five years would be quite sufficient to enable these industries which were considered to be necessary on military grounds to establish themselves. In view of all that they had heard in recent months about the stabilisation of the European position as a result of the Locarno conversations, which it was hoped would soon be embodied in a fixed treaty, he submitted that the grounds on which Part I. of the Safeguarding of Industries Act was put forward were now completely inapplicable, and these provisions ought not to be re-enacted. It was not only proposed in this clause to continue the duties that had been in operation since 1921, but also gradually to extend the range of the articles subject to duty, and also, perhaps, to increase the rates of duty. Six thousand articles were dutiable under the provisions of the 1921 Act, and now that number was to be greatly increased, particularly under a provision which was bringing in all separate components and elements of the dutiable articles. In addition the duty was to be raised from 33⅓ per cent. to 50 per cent. on the greater part of the articles. There must be something very seriously wrong with a number of these industries if, in spite of five years artificial feeding by a subsidy from the consumers in this country, they were still unable to compete with their rivals on the continent of Europe, who had been going through a period of very much greater difficulty than the manufacturers of this country. He noticed—and he thought that it was significant—that in two or three places in the Report of the Board of Trade Committee reference was made to the inadequacy of the arrangements for research in the British industries concerned. With regard to optical instruments, laboratory porcelain, and standard electrical instruments, the Committee admitted that British manufacture was very much behind hand in research and the coördination of research and manufacture. The policy of 1921 has evidently failed to produce the results required.

Sir P. CUNLIFFE-LISTER (President of the Board of Trade) said that every single section of the House had at one time or another been committed to this policy, and rightly so, because every one of these industries was an essential one, not only in war, but also in peace. On a matter of scientific efficiency the view pronounced by men like Sir Richard Glazebrook, Director of the National Physical Laboratory, and Sir William Pope, who he thought by common consent was the greatest living chemist to-day, would carry great weight. He would like to express the gratitude of the Government to Sir Arthur Colefox, and the two great scientists he had mentioned, for a very exhaustive and valuable inquiry. But of course this did not come only as the considered opinion of the Committee, but also as that of the three fighting Services as to what was absolutely vital to them as well as to the peace-time industry of this country. So far from there being inefficiency the record of these industries showed improvement in quality, in research, and also steadily falling prices. Our pre-war production of fine chemicals was about 10 per cent. of our consumption; to-day we were producing something like 75 per cent. There was an extraordinary advance not only in quantity, but also in quality, and an export trade was beginning as well. Take insulin, a vitally important drug. In insulin, which they had entirely developed under the protection of these duties, this country had now a very large share not only of the home market, but of the world market as well. The quality was quite excellent. He took it that was why the foreigner was buying it. The development of this fine chemical industry had made an opening for our scientific men and chemists, and there were now three or four times as many skilled chemists employed as ever before. Prices were falling all the time, and the fall was most marked wherever there was competition with a foreign monopoly. Optical glass and optical instruments were absolutely vital to all the three Services. They were equally important to medical and scientific research. When Dr. Gye and Mr. Barnard, whose researches were so well known, were making researches into cancer and required a particular kind of microscope in their experiments, which had never been made and which had to be specially designed, it was a British firm of optical instrument makers who at a very early date were able to produce what was wanted. Originally they were only interested in optical instruments for the purposes of war, and, of course, for medical research. The use of optical instruments for the testing of a number of products in industry was steadily growing. Everyone knew the value of X rays in detecting any faults in the human body. The X rays to-day was being used to detect hidden faults in the inside of almost every kind of article used in industry. If they took the chemical industry and the glass industry, it was common knowledge that in the great producing countries of the continent and the United States the capacity for production was greater than the output at present, and it would be perfectly simple if the Government withdrew the protection from these essential industries for foreign firms to produce on a larger scale which would suit them very well and to dump the surplus of their products in this country. They would be criminal if they did not continue for a reasonable period the full security and protection which had been so successful, not only in the case of these industries, but of other industries which depended upon them.

The amendment was rejected by 282 votes to 152.

An amendment proposed by Mr. GILLETT to limit the period of safeguarding to two years was negatived by 286 votes to 153.

Mr. PETHICK-LAWRENCE moved to leave out Subsection (2) of Clause 10, which raises the duties on optical glass and other goods to 50 per cent. of the value from May 1st, 1926. He said that glass was used for medical purposes, for research in hospitals in time of peace. The people who used that glass for these purposes wanted to secure it at a reasonably cheap price and if they were going to put an embargo, or at any rate a tariff, on the importation of efficient glass at a reasonable price from abroad, they were not benefiting as was suggested these users, but were injuring and to a certain extent crippling them on what they wanted to do. For hospitals and medical research efficient optical instruments were needed, and in order that the optical instrument industry might reduce its overhead charges and flourish they needed to get cheap materials. No one could pretend that if they put a tariff of 50 per cent. on the import of foreign glass they were going to enable these industries to get that glass more cheaply.

Sir P. CUNLIFFE-LISTER said that the more they produced the cheaper the product would be. The prices of these articles, which it was very difficult to produce cheaply, were only from 20 to 40 per cent. above pre-war prices, which, on the whole, was lower than the average rise in the price of other articles.

The amendment was negatived by 243 votes to 130.

Mr. PETHICK-LAWRENCE moved the omission of Subsection (3) of the clause, which adds to the Schedule of the Act the component parts of such optical instruments and scientific instruments as are chargeable with duty—amorphous carbon electrodes (but not including primary battery carbons or arc lamp carbons) and certain chemicals—and increases the duty on component parts of optical instruments from one-third to one-half of the value of the goods.

Mr. J. HUDSON, in supporting the amendment, said that it was not likely, even with very considerable scientific development, including the development of medical research, that in years to come there could be any return to the inordinate demand for the instruments dealt with in this section which was produced by the late war. In these circumstances one might ask what the Government expected to accomplish by putting on a duty of this sort.

Sir BURTON CHADWICK said a supply of optical glass and instruments of the first quality was essential to the prosecution of research in many very important branches of science. If there had been a serious fall in the optical industry it could be attributed largely to the immense accumulation of war surpluses of optical instruments which had not yet been used up in every belligerent country. That had produced an immense world reduction in the output of optical instruments and glass, and so the development of our optical production had generally been on a lessening scale in the years during which the 1921 Act had been in operation, but from their examination of the subject they found that the duty imposed had been of such value to the trade that it had actually saved it, in the opinion of the Board of Trade, from extinction. They believed that the duty which they were trying to impose would stimulate and develop the industry and help the British manufacturer to hold his own in competition with other countries. He believed that the industry was on the verge of a very much more prosperous condition. Safeguarding had not increased the price of one single item.

The amendment was negatived by 240 votes to 128.

Clause 10 was added to the Bill by 233 votes to 111 and progress was reported.

### WEDNESDAY, JUNE 9TH.

### *Septicæmia following Childbirth.*

Mr. PETHICK-LAWRENCE asked the Minister of Health whether his attention had been directed to the death of Mrs. Lily Maxwell from septicæmia following childbirth and to the comments of the Kingston coroner relating thereto, and whether he proposed to hold an inquiry into the case.—Sir KINGSLEY WOOD (Parliamentary Secretary of the Ministry of Health) replied: My right hon. friend's attention has already been called to this case and an inquiry is now being made by one of the medical officers of his department.

### *Open Spaces and Recreation Grounds in London.*

Sir HARRY BRITTAIN asked the Minister of Health if he would inform the House what efforts were being made by his department to secure open spaces and recreation grounds for the inhabitants of Greater London and for the districts immediately adjoining this area.—Sir KINGSLEY WOOD replied: The initiative in this matter rests with the local authorities. In so far as loans for the acquisition of land are subject to the consent of his department, my right hon. friend is willing to consider applications sympathetically, but loans may be delayed in some cases by heavy rates and the present need for economy. I may add that my right hon. friend has made a practice of urging local authorities to reserve land for open spaces in their town-planning schemes.

### THURSDAY, JUNE 10TH.

### *Medical Officers of Pensions Ministry.*

Mr. ROBERT YOUNG asked the Minister of Pensions how many medical men were now employed by his department throughout the country as medical referees or in any other capacity; what fees were paid; what was the total cost per annum; and whether the appointments were whole or part time.—Major G. C. TRYON replied: There are 338 medical officers now in the regular employment of the Ministry, of whom 252 are employed in a full-time and 86 in a part-time capacity. Of the full-time officers 50 are Permanent Civil Servants and the remainder are serving under contracts of temporary service varying from one month to three years. The total cost of these officers for the financial year ended March 31st, 1926, was £201,185, and the estimated cost for the current financial year is £222,240. In addition to the medical staff in regular employment it is still necessary to have frequent recourse to the assistance of private medical practitioners who act as examining medical officers (formerly described as medical referees), members of medical boards, supervisors of clinics, visiting surgeons, anæsthetists, &c., and are paid fees varying from £5 5s. to 5s., according to the nature of the services rendered. The total number now employed is 1752, and the fees paid during the financial year ended March 31st last amounted to £230,110.

### *Crown Nominees on the G.M.C.*

Viscount SANDON asked the Vice-Chamberlain of the Household, as representing the Lord President of the Council, on what dates the appointments of the Crown nominees to the General Medical Council lapse; and whether he could undertake that they would then be filled by non-professional persons.—Major HENNESSY replied: The dates of expiry of the terms of office of the Crown nominees (other than that of Mr. Hilton Young recently appointed) on the General Medical Council are as follows: Sir Edward Coey Bigger, Jan. 23rd, 1927; Sir Nestor Tirard, March 2nd, 1927; Sir William Leslie Mackenzie, Oct. 27th, 1927; and Sir George Newman, Oct. 8th, 1929. It is not possible to say in advance what action the Lord President of the day may see fit to take when the occasion arises for filling these vacancies.

### *Maternity and Child Welfare in Welsh Mining Areas.*

Mr. BARKER asked the Minister of Health if he was aware that the Welsh Board of Health were advising that no relief under the maternity and child welfare scheme be given to relieve distress arising out of the dispute in the mining industry but that such relief be given by the guardians of the poor, and that the Newport (Monmouthshire) Poor law union protested against this additional burden being placed on the funds of this union without any additional grant-in-aid; and would he consider cancelling this policy.—Mr. NEVILLE CHAMBERLAIN replied: It is no part of the maternity and child welfare scheme to relieve distress. Milk can only be supplied under that scheme to mothers and young children who are certified to need such a supply on medical grounds. The policy which has been adopted in this matter by the Welsh Board of Health on my instruction is as follows: While there should be no discrimination against the wives or children of men involved in the present dispute, no additional expenditure beyond that already approved for the supply of milk during the current financial year can be recognised for the Exchequer grant-in-aid. If, therefore, a maternity and child welfare authority spend more money on milk because of the dispute, the additional expenditure must be found out of the rates, but the better course would be that the distress arising out of the dispute should be dealt with by the guardians. I see no reason to modify or cancel this policy.

### FRIDAY, JUNE 11TH.

### *The Sale of Certified Milk.*

Mr. DUCKWORTH asked the Minister of Health whether, in connexion with the sale of Certified milk, he would consider the desirability of authorising the use of tin caps instead of paper caps and seals, in view of the cost of the latter method, which debarred many producers from applying for the Ministry's licence.—Mr. NEVILLE CHAMBERLAIN replied: There is no objection to the use of suitable metal caps for the sealing of bottles containing Certified milk and a number of producers are at present using such caps. Officers of the department are prepared to advise as to the suitability of any particular cap.

### *Adulteration and Sale of Impure Foods.*

Colonel DAY asked the Minister of Health what further steps he proposed to take for the protection of the public against the adulteration and selling of impure foods.—Mr. NEVILLE CHAMBERLAIN replied: I propose shortly to make a Milk and Dairies Order which I hope will secure a further improvement in the condition of the milk-supply. As the hon. Member is aware, regulations restricting the use of preservatives in food have recently been made and will come into operation next year. I am not contemplating any immediate enlargement of the powers of the local authorities responsible for the administration of the existing law as to the sale of food and drugs.

## MONDAY, JUNE 14TH.

### *Special Women Factory Inspectors in India.*

Mr. THOMAS HENDERSON asked the Under Secretary of State for India whether the Government of India had received any representations from provincial legislative councils as to the need that was alleged to exist for the appointment of special women factory inspectors; and, if so, whether the Government proposed to take any steps to induce local governments to make such appointments.—Earl WINTERTON replied: The Government of India have directed the attention of the Provincial Governments to the recommendation of the International Labour Conference of October, 1923, favouring the appointment of women for certain classes of factory inspection work, and have expressed the hope that in the larger Provinces it will shortly prove possible to make an advance in this direction. No report has yet been received of the action, if any, which has been taken by Provincial Governments.

### *The Indian Medical Service.*

Sir RICHARD LUCE asked the Under Secretary of State for India whether any decision had yet been reached as to the future of the Indian Medical Service; and, if so, if he could give any details as to that decision.—Earl WINTERTON replied: My noble friend hopes to receive the Government of India's final proposals very shortly.

### *Appointments as Factory Surgeons.*

Mr. HORE-BELISHA asked the Minister of Health what was the present procedure in the appointment of certifying factory surgeons by the Home Office; and whether he was satisfied that this procedure was the best calculated to obtain a proficient and efficient medical service.—Sir W. JOYNSON-HICKS replied: The appointments in question are made by the Chief Inspector of Factories under Section 122 of the Factory and Workshop Act, 1901. Vacancies as they occur are advertised in the *London Gazette* and communicated to the medical press, and applicants are required to give particulars of their qualifications and experience and of any other appointments they may hold. The applications are carefully scrutinised and inquiries made, and, in the case of important districts arrangements are made for the candidates to be interviewed by one of the medical inspectors. Where there is more than one candidate, the advice of the Senior Medical Inspector is taken. The Chief Inspector is satisfied that under this procedure the best men available are secured, and I have received no complaints.

### *Maternity Centres and Birth Control.*

Mr. THURTLE asked the Minister of Health if, in view of recent events, his department had reconsidered the question of permitting the giving of birth control information at maternity and child welfare centres.—Sir KINGSLEY WOOD replied: No, Sir.

### *Indian Army Veterinary Corps.*

Mr. LANSBURY asked the Under Secretary of State for India whether Indian candidates for commissions in the Indian Army Veterinary Corps must pass through the Dehra Dun Military College; and whether the capacity of this college was equal to the demands made by Indian candidates for commissions.—Earl WINTERTON replied: I have no doubt that the Government of India will be willing to consider candidates who have not passed through the Dehra Dun College provided that they are members of the Royal College of Veterinary Surgeons and are fully qualified in other respects. It is within the capacity of the Dehra Dun College to produce candidates for the small number of ents which it is desired to fill from this source in addition to its primary function of producing candidates for the Indian vacancies at Sandhurst.

### *Animals and Poison Gas Experiments.*

Captain WEDGWOOD BENN asked the Secretary of State for War whether he could explain why no less than 2131 animals, as disclosed by the War Department, were subjected to gas poisoning experiments in this country between May, 1923, and January, 1926; and whether, in view of the Washington Conference Treaty, 1922, and the Geneva Protocol, 1925, against the use of poison gas in warfare which had been ratified by 31 States, it was necessary to continue these experiments.—Sir L. WORTHINGTON-EVANS replied: Experiments with animals are, unfortunately, essential in order to obtain the necessary data for ensuring adequate defence against poison gas and for evolving efficient methods of treating gas casualties. As regards the second part of the question the Government does not feel that the Agreements referred to justify it omitting to take all possible precautionary measures to protect the Forces of the Crown and the inhabitants of the country against gas attacks in war and for this reason the experments referred to must continue.

## TUESDAY, JUNE 15TH.

### *Recruiting of Service Medical Officers.*

Lieut.-Colonel FREMANTLE asked the Prime Minister if the Government had arrived at any decision as to the recruiting of medical officers for the Navy, Army, and Air Force.—Mr. BALDWIN replied: Yes, Sir. The Government have considered the Report of the Committee appointed last autumn to consider questions relating to pay and other matters affecting recruitment of officers and nurses to the medical branches of the fighting Services and have decided to give effect to its recommendations as from July 1st next. —Lieut.-Commander KENWORTHY: Are the Government contemplating amalgamation of the three medical services? Mr. BALDWIN: No, not that I am aware of.—Lieut.-Colonel FREMANTLE: When shall we get details of this decision?—Mr. BALDWIN: The necessary orders, I understand, are to be published forthwith.

---

BOLINGBROKE HOSPITAL, WANDSWORTH COMMON. The report for 1925, which has just been issued, states that in addition to the William Shepherd Memorial Wing, which is approaching completion, it is proposed so to reconstruct the out-patients' department that the ear, nose and throat, and eye departments may be modernised, to provide a second theatre and a pathological laboratory. The governors state that these additions have become of vital importance, the total number of patients having surpassed all previous records.

PRESENTATION TO PROF. SAHLI.—On May 27th Dr. Hermann Sahli, Professor of Medicine in Berne, celebrated his seventieth birthday, and was presented with a festive publication containing 57 original papers from pupils of his clinic. Dr. Sahli was only 32 years old when the Bernese Government nominated him to fill the chair of clinical medicine, and for nearly 40 years has been the centre of the scientific teaching of clinical medicine in Switzerland, while his standard work on clinical examination methods has made his name known all over the world. He is the survivor of the trio which included Kocher and Langhans, and drew numberless foreign students to the Berne school.

SOCIETY OF CHEMICAL INDUSTRY.—The forty-fifth annual meeting and Congress of Chemists will be held in London from July 19th to 23rd, under the presidency of Mr. W. J. Uglow Woolcock. A full programme has been arranged. The functions include the presentation of the Society's Messel Medal to Lord Balfour, F.R.S., on July 19th, at 2.30 P.M., after which the Messel Memorial Lecture will be delivered by Lord Balfour. At 11 A.M. on July 20th a joint meeting of the Biochemical Society with the London Section of the Society of Chemical Industry will be held at the Great Central Hotel, when the scientific and industrial problems presented by the hormones—the natural drugs of the body, will be discussed, Sir Alfred Mond presiding. Papers will be read by Dr. H. H. Dale, Sec.R.S., on the Experimental Study and Use of Hormones; Dr. H. W. Dudley on the Chemistry of the Pituitary Gland and of Insulin; Mr. F. H. Carr on the Commercial Production of Hormones; Dr. H. A. D. Jowett on the History of Adrenalin; Prof. G. Barger, F.R.S., on Recent Progress in the Chemistry of Thyroxine, and Dr. J. W. Trevan on Biological Assay of Hormones. Among the works and laboratories visited will be the National Physical Laboratory, Teddington; Burroughs, Wellcome and Co., chemical works, Dartford; British Drug Houses, City-road; Imperial College of Science and Technology, South Kensington; Chemical Laboratories, University College.

Certifying Surgeons under the Factory and Workshop Acts: ARMSLEY R., L.R.C P *Lond.*, M.R.C S (Carnforth), MARSHALL, R., M B., Ch.B Glas. (Biggar, Lanark).

# Vacancies.

*For further information refer to the advertisement columns.*

*Association of Surgeons of Great Britain and Ireland, 51, Wimpole-street, W.*—£350 Surgical Scholarship.
*Aylesbury, Ryl. Buckinghamshire Hosp.*—Res. M.O. at rate of £200.
*Cambridge Physiology School.*—George Henry Lewes Studentship. £250.
*Cape of Good Hope.*—M.O.H. £1100.
*Cape Town, Somerset Hospital.*—Supt. £1000.
*Chelsea Hospital for Women, Arthur-street, S.W.*—Hon. S. to Ear, Nose, and Throat Dept.
*Chesterfield and North Derbyshire Royal Hospital.*—Fifth H.S. At rate of £100.
*Cheyne Hospital for Children, Chelsea, S.W.*—Hon. Surg.
*Doncaster Royal Infirmary.*—Third H.S. At rate of £150.
*Dreadnought Hospital, Greenwich.*—H.P. and H.S. Each at rate of £110. Also P.
*Durham County Sanatorium, Wolsingham.*—Locum. £40 a month.
*Evelina Hospital for Children, Southwark, S.E.*—Hon. Dental S.
*Exminster, Devon Mental Hospital.*—Jun. Asst. M.O. £300.
*Indian Research Fund Association, Simla.*—Research Workers on Malaria, also Entomologist. Each at rate of Rs.1500 per mensem.
*Ipswich, East Suffolk and Ipswich Hospital.*—H.P. and Three H.S.'s: Each £100.
*King George V. Sanatorium, Goldalming, Surrey.*—Jun. Asst. M.O. £500.
*Liverpool, Eye and Ear Infirmary, Myrtle-street.*—H.S. £100.
*London Hospital, E.*—First Asst. to Children's Dept. £400.
*London Temperance Hospital, Hampstead-road, N.W.*—Cas. O. At rate of £120. Also H.P. At rate of £100.
*Macedonia, Friends' Council for International Service.*—Medical Work. £14 per month.
*Manchester Radium Institute, Nelson-street.*—Asst. Radiologist.
*Manitoba University.*—Asst. Prof. of Anatomy. $3,000.
*National Hospital, Queen-square, W.C.*—Asst. P.
*Plymouth, South Devon and East Cornwall Hospital.*—Jun. H.S.
*Portsmouth, Royal Hospital.*—Cas. O. At rate of £100.
*Queen's Hospital for Children, Hackney-road, E.*—Cas. O. At rate of £100.
*Reading, Royal Berkshire Hospital.*—Three H.S.'s. At rate of £150.
*Royal Free Hospital, Gray's Inn-road, W.C.*—Cas. O. £150.
*Royal London Ophthalmic Hospital, City-road, E.C.*—Sen. H.S. At rate of £150. Also Refraction Asst. At rate of £100.
*Royal Northern Hospital, Holloway, N.*—Asst. Surg. O. £75.
*Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.*—Hon. Med. Reg.
*St. Bartholomew's Hospital Medical College.*—Sen. Demonstrator and Demonstrator of Physiology.
*Sheffield, Jessop Hospital for Women.*—Sen. Res. O. £250. Also Asst. H.S. At rate of £100.
*Sheffield Royal Infirmary.*—Two H.S.'s., H.P., Asst. Cas. O. and Ophth. H.S. All at rate of £80.
*Sheffield, South Yorkshire Mental Hospital.*—M.O. £400.
*Southampton, Free Eye Hospital.*—Locum Tenens Ophth. H.S.
*Sudan Medical Service.*—Four M.O.'s. £E.720.
*University of London.*—External Examiners.
*Virol Ltd.*—Research Scholarship in Clin. Pathology. £200.
*Westminster Hospital, Broad Sanctuary, S.W.*—Asst. Med. Reg. and Asst. Surg. Reg. Each at rate of £50. Also Asst. S. to Ear, Nose, and Throat Dept.

# Births, Marriages, and Deaths.

## BIRTHS.

Cairns.—On June 8th, at Woodcroft, Loughton, the wife of H. W. B. Cairns, M.B., F.R.C.S., of a son.

Shepherd.—On June 8th, at St. Andrew's-crescent, Cardiff, the wife of Dr. C. W. Shepherd, of a son.

Urwick.—On June 11th, Joan Bedford Urwick, L.R.C.P., M.R.C.S., the wife of L. Urwick, of Lawn-road, Hampstead, N.W., of a daughter.

## MARRIAGES.

Brown—Bannerman.—On June 9th, at All Saints' Church, High Wycombe, Walter Graham Scott Brown, M.B., B.Ch., to Margaret Affleck Bannerman, M.B., B.S., only daughter of Dr. and Mrs. G. D. K. Bannerman, of Riversdale, High Wycombe.

Gray—Carr.—On June 12th, at Hampstead, Oliver Gray, M.B., Ch.B., to Marjorie Howard, eldest daughter of Mr. and Mrs. Francis H. Carr.

Taylor—Ross-Johnson.—On June 10th, in London, Julian Taylor, O.B.E., M.S., F.R.C.S., to Edith Margaret Ross-Johnson, M.B., B.S., M.R.C.S., L.R.C.P.

## DEATHS.

Charlesworth.—On June 5th, at his residence, Hastings-road, Ealing, Henry Charlesworth, C.M.G., Brevet-Colonel (late R.A.M.C. retd.).

Cotes.—On June 10th, at a nursing home, Plymouth, following operation, Digby Francis Baynes Cotes, M.R.C.S. Eng., &c., of Week St. Mary, aged 63 years.

James.—On June 7th, Stanlake James, M.R.C.S., L.R.C.P., of St. John's-road, Putney, aged 61.

Morris.—On June 14th, at Connaught-square, Hyde Park, W., Sir Henry Morris, Bt., aged 82.

Mott.—On June 8th, at the General Hospital, Birmingham, Sir Frederick Walker Mott, K.B.E., M.D., LL.D., F.R.S., F.R.C.P., of Nottingham-place, W., aged 72.

# Notes, Comments, and Abstracts.

## THE TECHNIQUE OF RADIUM THERAPY.

At the Radium Institute, London, inquiries are frequently received as to the precise methods adopted in the treatment of various cases. It has therefore been thought expedient by the medical superintendent, Mr. A. E. Hayward Pinch, to publish a short manual of technique in radium therapy as a supplement to the "Clinical Index of Radium Therapy" which was published in 1925. The procedures described and illustrated are those used at the Radium Institute. It is not claimed that they are necessarily the best methods, but they are found in practice to give satisfactory results.

The book, of which any practitioner may obtain a free copy on application to the secretary at the Institute (Riding House-street, London, W. 1) contains some 40 pages and the same number of plates. It is divided into nine chapters headed respectively: General Considerations; Precedent Operations; Handling of Radium Apparatus; Surface Applicators: their Use in Special Situations; Tube Apparatus; Preliminary Measures; Insertion of Tubes; Use of Tube Apparatus in Special Situations; Complications and Sequelæ.

The summary of its contents, given below, is notexhaustive, but will serve to indicate its general scope and to point out some observations of especial interest. The need for much clinical experience and surgical skill on the part of the radiologist and the advantages of coöperation with surgical colleagues, are emphasised throughout. Another point of importance which is apt to be overlooked is that the general health of all patients should be brought to as high a standard as possible before radium treatment is commenced. The principal conditions which militate against successful radium therapy include anæmia, cachexia, and diabetes. Inflammation, sepsis, and previous X ray treatment are also contra-indications to radium therapy under the following conditions:—

*Inflammation.*—Tissues while acutely inflamed should not be subjected to radium irradiation, as it is impossible accurately to predict the extent and degree of the resultant reaction under such conditions. A more or less complete subsidence of the active inflammatory process must be secured before radium treatment is given. The chronic inflammatory changes, accompanied by dense leucocytic infiltration, which are frequently met with at the growing edges of malignant tumours are, on the other hand, favourably influenced by radium irradiation, and their resolution is often speedily induced.

*Sepsis.*—This complication is a frequent and very harmful one, and is specially apt to prove troublesome in the mouth, larynx, vagina, and uterus. Attempts should be made to secure a condition of surgical cleanliness before radiation. The removal of sloughs, the opening and cleansing of sinuses and abscesses, followed by repeated and regular irrigation of the regions with suitable antiseptic solutions, should be carried out for several days prior to the use of radium, or an increase of the septic process will follow.

*Previous X Ray Treatment.*—Areas which have been subjected to many X ray exposures are often leathery, avascular, and devitalised, and have little power of satisfactory repair. When treating such sites the dosage administered should be distinctly low or the tissues may break down over a wide area, giving rise to a painful and intractable ulceration.

### *Precedent Operations.*

Before subjecting a patient to radium treatment it is often advisable to perform some operation, either in order to remove a source of irritation or for some other purpose. Such operations include extraction of teeth and removal of diseased bone before treating epithelioma of the tongue, mouth, or jaw; tracheotomy, to enable a prolonged intra-laryngeal exposure to be given, or as a precautionary measure against œdema in growths in the inferior pharyngeal, laryngeal, or post-cricoid regions; gastrostomy, in carcinoma of the œsophagus; colostomy, in growths of the sigmoid flexure or rectum; and cystostomy, in cases of carcinoma of the bladder of long standing.

### *Radium Apparatus.*

Frequent contact with radium and radon apparatus, even though the period of each manipulation be of extremely short duration, will sooner or later induce definite inflammatory and trophic changes in the fingers and hands of the workers, unless certain precautions are rigidly adhered to. The changes are due to the cumulative effect of small repeated doses of radiation, principally of the beta type. All apparatus should be handled with wooden or rubber-covered metal forceps, at least a foot in length, and the hands should be protected with leather gloves. Tubes and needles whilst being threaded should be held with specially adapted forceps, the silk employed having been treated with hard paraffin wax. No nurse or attendant should be allowed to make up or prepare apparatus daily for a period of time exceeding three months, and an equal or even longer period of rest from contact with radium must be given before the work is resumed. As an additional precaution against the cumulative effect of the gamma radiation, which in susceptible subjects may initiate general disturbances—anæmia, amenorrhœa, &c.—the workers should sit at a table which is covered with lead 5 cm. in thickness, a leaden breast-plate being applied to the edge of the table of such height as completely to cut off all emergent rays from the body and head of the workers. The stock of radium should be kept in a separate room, situate as far as possible from the radium workroom, to which short visits should be paid at need. Apparatus when prepared for use should be placed immediately in carrying boxes lined with thick lead and provided with a long, stout leather sling. Emanation tubes and seeds are conveyed from place to place in a special shaped carrier.

*Surface Applicators* are used (1) unscreened or lightly screened, for the treatment of superficial growths and conditions; (2) heavily screened, and emitting only the gamma radiation, for employment in deep radium therapy. Their size ranges from 1 to 30 square cm., and their shape may be circular, square, or rectangular. They are usually made with radium sulphate. It is also possible to utilise radium tubes as surface applicators by means of shallow leaden trays filled with hard paraffin wax melting at 60° C. The tray is laid upon a hot plate until the wax melts, the tubes are placed in the melted wax, their number and spacing being regulated by the activity desired, the tray is then removed from the hot plate, and the wax speedily cools and solidifies, retaining the tubes securely in accurate position. With growths of irregular and uneven outline, dental modelling compound is of particular value, as it enables the disposition of the tubes to be made in such fashion as to secure the most effective radiation. The Institut du Radium at Paris employs an embedding compound made of beeswax 100 g., paraffin wax (melting at 62° C.) 100 g., pine sawdust 20 g. This can be worked quickly and cleanly, and is most useful when treating a large surface area with applicators of any kind.

General directions for the use of surface applicators are given and also detailed directions for the use of surface applicators in special situations such as the orbit, the mouth, the breast, the thorax and abdomen, and the vulva, perineum, and anus.

*Tube Apparatus.*—The five principal forms of tube apparatus are needles, cylinders, "hour-glass" tubes, "window" tubes, "sleeve" tubes, and "seeds."

*Needles* are used for actual insertion into the substance of growths. Those in general use at the Institute have walls of silver 1 mm. in thickness, or platinum 0·8, 0·4, or 0·5 mm. in thickness. One extremity is pointed, the point being of iridium in the platinum tubes. The other extremity is closed with an eyeletted stopper, or a screw thread, into which a pliable silver wire can be inserted. The length of the tubes ranges from 1 to 3 cm., and their diameter from 0·9 to 2·2 mm. They contain from 1 to 25 mg. of radium element.

*Cylinders.*—These tubes have a blunted free extremity, and are closed by an eyeletted stopper or screw thread. They are employed chiefly for the radiation of cavities—e.g., bladder or uterus—and have walls of 2 mm. of lead or 1 mm. of silver. They vary from 1 to 6 cm. in length, and from 3 to 7 mm. in diameter. They contain 12·5, 25, or 50 mg. of radium element.

*"Hour-glass" Tubes* are of special service in the treatment of malignant strictures of the œsophagus or rectum, being easily retained in accurate position. They have walls of 2 mm. of lead or 1 mm. of silver, and are made in lengths varying between 2 and 10 cm. Their charge is usually 50 mg. of radium element.

*"Window" Tubes.*—A leaden tube with walls 2 mm. in thickness has a window occupying one-third of its circumference. This gap is closed with a screen of 0·1 mm. of lead, 0·5 or 1·0 mm. of silver. A tube of radium salt or radon is inserted into the tube, which is placed so that ulcerated or fungating portions of the growth receive the lightly filtered radiation, and the remainder the heavily filtered rays.

*"Sleeve" Tubes.*—A silver tube with walls of 0·5 mm., inserted in a collar or sleeve of lead, 1·5 or 2·0 mm. in thickness, which encircles half or two-thirds of its length, is useful in the treatment of small localised ulcerated recurrences in the vaginal vault after hysterectomy.

Radon may be used instead of radium element in any of these tubes.

*"Seeds."*—This term is applied to tiny capillary glass tubes, 2 to 3 mm. in length and 1 mm. in diameter, which are charged with 1 to 2 millicuries of radon, and permanently buried in growths, unscreened. One millicurie emits 132 millicurie-hours of radio-activity in its passage to complete decay. The excessive fragility of these "seeds" necessitates the use of special apparatus for their insertion.

### *Measures Preliminary to Treatment by Radium.*

*Aspiration* is necessary or advisable before treating cystic or caseating growths—e.g., cystic hygromata or caseating tuberculous glands. In growths affecting the maxillary antrum or nasal fossæ, and in morbid conditions of the uterine mucosa, a preliminary *curettage* is often advantageous. Exuberating fungating growths of the palate, fauces, lip, vulva, and cervix are particularly suitable for preliminary treatment with the *diathermy* knife or button. Cases of annular carcinoma of the œsophagus or rectum sometimes require *dilatation* before a radium tube can be inserted. *Douches* of tr. iodi. ʒi to 1 pint of warm water, t.d.s., may be required for patients suffering from ulcerated carcinoma of the uterus. If the iodine douche prove irritating, glycothymoline (1–20) may be substituted. The two last douches before radium is inserted should be of flavine, 1 in 2500.

*Local Anæsthesia.*—The most generally useful local anæsthetic is a solution of cocaine and adrenalin, injected hypodermically. Cocaine hydrochlor. 10 per cent. solution, is of great value when inserting tubes or needles into the pharynx, palate, fauces, or tonsils. Novocaine 5 per cent. is to be preferred for the urethra, vulva, anus, and rectum.

*General Anæsthesia.*—Nitrous oxide gas and oxygen is the combination of choice; but if deep muscular relaxation is necessary a mixture of chloroform and ether (open method) may be used. Endotracheal insufflation by the double tube method is useful in growths involving the upper respiratory tract, and in operations below the level of the umbilicus spinal analgesia by stovaine is valuable.

### *The Technique Employed.*

Mr. Pinch gives a succinct account of the technique employed in the insertion of tubes for surface growths by special forceps with longitudinal grooves, by trocar, cannula, and plunger, and by means of a stiff but pliable silver wire attached to one extremity of the tube. Wood's fusible alloy is employed in the connexions between wire and tube when the tubes are inserted into cavities such as rectum or bladder. This alloy melts at 60° C. and is used to seal the stopper in the screw-threaded mouth of the tube. The distal end of the screw stopper is attached to the pliable silver wire by means of ordinary solder (melting-point 170° C.). When it is desired to remove the radium container from the interior of the tube its attached extremity is gently heated in a gas flame until the fusible alloy melts, when the stopper is readily unscrewed and the tube emptied of its contents. The excessive fragility of "seeds" necessitates the employment of a special form of applicator—a simple and effective one being a trocar and cannula of very fine bore.

A *discussion* follows on the use of tube apparatus in special situations, including nose, mouth and tongue, pharynx and fauces, larynx, œsophagus, stomach, colon, rectum, uterus, bladder, prostate, and urethra. These sections can hardly be summarised with advantage, for the significance of the advice depends on details.

### *Complications and Sequelæ.*

*Bacterial Infection.*—Radium irradiation appears definitely to lower the resistance of some patients to any kind of pyogenic infection for two or three weeks, and an acute inflammatory condition, almost erysipelatoid, may supervene. For inflammation on an unexposed part of the body collosol ichthyol ointment is useful; for the face, neck, or hands a good cold cream containing boric acid, or a small amount of hydrarg. amm. chlor. is recommended.

*Telangiectasis.*—Some degree of telangiectasis will almost inevitably follow periodic radium irradiations of any area of the skin. Untreated telangiectases tend to get larger, so that if they are situated in face, neck, or hands they should be treated carefully with a fine-pointed electric cautery.

*Pigmentation* occurs less frequently than telangiectasis, and in the early stages may be lessened by application of weak bichloride of mercury and glycerine lotion. Its development is aggravated by exposure to sunlight, and affected areas should be protected with grease paint in bright weather.

*Ulceration.*—A somewhat intractable superficial ulceration is occasionally noted over the surface of nævoid lesions which have received numerous treatments. Treatment should be interrupted for at least six months, and any subsequent exposures should be of shorter duration and given at longer intervals.

*Annular fibrosis* results from frequent repetition of exposures with heavily-screened tube apparatus within cavities, notably the rectum and vagina. It requires regular dilatation or may ultimately cause occlusion of the canal.

*"Radium Burns."*—This term should not be applied to the vesication and ulceration following an unscreened

radium exposure. Here a destructive reaction has been deliberately produced and satisfactory repair can be anticipated. The term should be reserved for the few instances in which the exposure and dosage have been prolonged and excessive, owing to accident, negligence, or ignorance. The ulceration is extreme, pain is severe and persistent, and repair always slow and frequently imperfect. The treatment of these true "radium burns" demands much patience. The ulcerated area is often covered by a foul tenacious washleather slough, the separation of which can be hastened by plugging the cavity daily for three or four hours with gauze soaked in a 1 in 4 solution of enzymol. On removal of the plugs the cavity should be irrigated with a 1–10 solution of hydrogen peroxide and gently dried. As a regular dressing, an ointment containing 5 per cent. of acid carbolic in a lanolin base, chloretone compound ointment, or emollientine (Parke, Davis and Co.) are of value. When the pain and tenderness have largely disappeared scarlet red ointment, or zinc ointment containing 2 per cent. of ferri subcarb. and 0·5 per cent. of argyrol is recommended. When granulation is active and repair is taking place, granulogen or collosol argentum pasta expedite healing.

## THE TEACHING OF SWIMMING.

*To the Editor of* THE LANCET.

SIR,—Last Easter there was a sad accident in the River Brent; two boys, who were paddling in it, stepped into a part which deepened suddenly and were both drowned; one boy was 14 years of age, the other 13; neither of them could swim. The education authorities do not undertake the teaching of swimming, but it is included in the education code as an approved physical exercise; only one or two elementary schools have their own swimming bath and only one or two municipalities have provided separate swimming baths for their school-children. However, swimming instruction has been taken up by the Amateur Swimming Association, and its education committee has prepared a small handbook,[1] fully illustrated, setting forth how to teach a class by land drill and in the water. It is recommended that children of 8 years of age or older be taught in classes of 5 and 20. A large number of school-children learn to swim, many of them very well, as may be seen at the schools' swimming galas in the autumn, but all the children do not learn; it may happen that there are so many children that they have to be sent in classes of 50, which is more than one instructor can teach in the allotted time, also that there is no place a second summer for the child who has not learnt the first, also that no land drill has been held.

They have a better way in the army schools: they send all their children in their ninth summer to their baths to be taught in classes of 20 by the swimming instructor; thus, all army children of 10 years of age can swim. This though good is not perfect; in British Guiana, the reed country of Irak, and the South Seas the children learn to swim as soon as they can walk; this is a great advantage, for during childhood they will enjoy bathing more and become better swimmers. The South Sea Islanders taught the Australians the crawl stroke, and they us.

English children can be taught to swim when quite young; her parents taught a little girl of 4 to swim, and a boy of 5 also could swim; a little girl of 5 floats in her domestic bath and can turn over in the water and pick up objects. 96 per cent. of children attend the elementary schools, the remaining 4 per cent. attend kindergarten or preparatory schools when young; only a few of these schools have their own swimming baths, but quite a small bath would be sufficient for teaching a few children at a time. Swimming once learnt, as Sancho Panza said, is never forgotten; it is good exercise, for it employs most of the muscles, and equally on the two sides of the body; it is a pleasant pastime, but little interfered with by rain, and inexpensive; but there are various grave dangers connected with it, and the public should, each summer, be warned of these; recently a girl of 13 was swimming in a public bath, she was seen to sink, was rescued, respiration was partially restored, but she died later.

I am, Sir, yours faithfully,

Putney, S.W., June 13th, 1926. WALTER EDMUNDS.

⁂ Mr. Edmunds's letter is well-timed for the beginning of the bathing season. The teaching of swimming should be an obligatory part of the educational curriculum of any island State. An important section of the great Dusseldorf Medical Exhibition is devoted to swimming on the ground that it stands first among healthy sports in hardening the body and making it resistant to disease. The slogan of this section might be taken over thus: "Every Briton a swimmer, every swimmer a life-saver."—ED. L.

## ADVICE ON MEDICAL ETHICS.

AT the annual meeting of the London and Counties Medical Protection Society (see p. 1232) the report, which was adopted, contained the following examples of serviceable advice given to members of the Society on ethical difficulties.

(1) A member wrote to the Society complaining that consultants saw patients of his without his knowledge, advising them and prescribing for them, and then writing to him informing him of what they had done. The member was advised that it had often been contended, with much force, that as a barrister will only advise through a solicitor, so a consultant should only advise through the patient's usual medical attendant, but that this was not the invariable custom in the medical profession. He was told, however, that it was desirable for a consultant to advise and prescribe through the medical attendant, if known, thus giving him an opportunity to discuss any change of treatment, &c., beforehand.

(2) A member inquired if it would be proper for him to take a radiogram for a patient who was consulting an osteopath, and to explain to the patient what it indicated. He was advised that by doing so he might be assisting an unqualified person to do work requiring surgical knowledge and skill. He was also told that it was understood that medical practitioners specialising in X rays declined to see patients except on the recommendation of a doctor, and that the films and reports were only handed to that doctor, and not in any case given to the patient. The member was advised that this seemed to be the correct procedure.

(3) A member wrote that an inquiry was to be held by a local ethical committee into an accusation of unethical conduct made against him. A complaint had been made against him by a medical practitioner that he had seen a patient of his otherwise than in consultation. It transpired that the patient had refused to continue under his usual medical attendant, and wished to change. The member was advised as to his defence, and was recommended to conduct his own defence, and not to be legally represented. After the inquiry the ethical committee decided that he had not offended against any ethical law and had not acted in any way contrary to the ordinary custom of the profession.

## CANADIAN MEDICAL DIRECTORY, 1926.

THE ninth edition of the Canadian Medical Directory and Physicians' Handbook, which has just reached us, contains alphabetical and topographical lists of some 9000 physicians, 2850 dentists, and 3000 druggists living within the Dominion. The volume opens with a section of 90 pages reciting the *Canadian Medical Act of 1880, the names of the Medical* Council and of the Board of Examiners, as well as instructions for registration and examination. A brief account is then given of each of the nine universities—Alberta, Dalhousie, Laval, Manitoba, McGill, Montreal, Queen's, Toronto, Western Ontario—with the professorial staff, examination regulations, and other academic information necessary for medical and dental students. The Directory itself, under the heading of each province, contains the medical laws and regulations in force locally, along with a list of hospitals, sanatoriums, medical and dental societies, and the personnel of the public health staff. The Physicians' Handbook consists of a compendium of useful information for quick reference, including the Narcotic Drug Act of 1923, a classified list of specialists, and an alphabetical list of chemists and chemical companies, and of dealers in druggists' sundries and physicians' and surgeons' supplies. The book is well indexed and easy of reference. In paper cover the price is 7 dollars; bound in cloth 8 dollars. It is published and printed by Messrs. A. P. Pigeon, Ltd., of 109, Ontario-street East, Montreal, Canada.

DR. Joseph Anthony Ferriero has been appointed by the King a Nominated Member of the *Council of Government of the Colony of Mauritius.*

PROF. S. Mallannah, of Osmania Medical College, writes that the Parel Laboratory at Bombay is likely to introduce some improvement in Haffkine's prophylactic fluid against plague. It has been found that the *clear filtrate or supernatant* fluid possesses greater antigenic value than the whole fluid, and hence the sediment is non-essential. Prof. Mallannah made a similar observation many years ago (*Indian Medical Record*, Jan 3rd, 1900). The filtrate does not give rise to the troublesome induration at the seat of injection, which may last for three or four months.

*West German Spas: Corrigenda.*—In the article on pp. 1164–65 of THE LANCET of June 12th, under Schlangenbad "steam bath" should read "*stream* bath," and under Wildungen the penultimate sentence by omission of two commas should read "*although* the water drinking and bathing are considered . . . ."

# The Oliver-Sharpey Lectures
ON
# CARBOHYDRATE METABOLISM IN HEALTH AND DISEASE.

*Delivered before the Royal College of Physicians of London*

BY HUGH MACLEAN, M.D. ABERD., D.SC. LOND., M.R C.P. LOND.,

PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON; DIRECTOR, CLINICAL MEDICINE UNIT, ST. THOMAS'S HOSPITAL.

## LECTURE II.*
*Delivered on May 6th.*

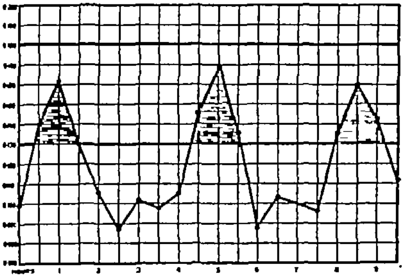
IN my last lecture it was indicated that the chronic *diabetes of the elderly patient is really not* diabetes at all but a diminished power for storing sugar, and that the chief organ concerned appears to be the liver. It is an interesting point that though storage of sugar in the body can be apparently upset without oxidation being interfered with, yet the converse is never true. Defective oxidation is apparently always *associated with defective storage.* Since defective oxidation of foodstuffs is the fundamental difficulty in diabetes, it follows that diabetes is necessarily accompanied by a difficulty in storage as well. Indeed, one of the very earliest indications of diabetes is an inability on the part of the organism to store sugar, and this defect can sometimes be *demonstrated at a stage when there is as yet* little or no evidence of any difficulty in oxidation. Clinically, this defective oxidation is best indicated by the presence of acetone and diacetic acid in the urine. In true diabetes these bodies are probably always present. It must not be considered, however, that the presence of these ketone bodies in urine *containing glucose necessarily* indicates that the condition is diabetes. Indeed, when acetone is tested for by Rothera's method, which is the test now universally employed, it is by no means uncommon to get a quite definite reaction in normal urine. The colour which develops is certainly more red than that produced by acetone, but even to the experienced *observer this complication* presents difficulties, and there is little doubt that many urines are supposed to contain acetone when acetone is really absent. The nature of the substance producing this anomalous reaction is at present unknown, but it differs from acetone in being non-volatile on boiling. In all suspicious cases, therefore, the urine should be *thoroughly boiled* before doing Rothera's test. If a reaction persists after boiling, the substance present is not acetone. There are various conditions besides diabetes in which glycosuria is accompanied by the presence of acetone in urine. The importance of this combination is very great, and an attempt will be made later to show how these conditions can be differentiated from true diabetes.

### RENAL GLYCOSURIA.

It has already been pointed out that in some individuals the renal threshold for sugar is so low that sugar may leak through the kidney, and yet no disturbance whatever of carbohydrate metabolism be present. Until comparatively recently it was thought that this renal glycosuria was of rare occurrence, but experience shows that it is really much more common than diabetes. Unfortunately, many patients suffering from this innocuous condition are still being treated as if they were suffering from diabetes. With modern means of investigating glycosuria there is no excuse for this, for the condition can always be diagnosed with *certainty* if the necessary care is taken. Since the normal renal threshold is in the region of 0·18 per cent. blood-sugar, and since the blood-sugar in every normal individual constantly rises very nearly to this point after meals, it follows that if the threshold is lower than normal, sugar will pass into the urine during the various periods of the day when the blood-sugar is high. In the healthy individual the daily variation in blood sugar might be represented by the curve. (Chart 1.)

Now, if in such an individual the threshold for sugar is in the region of 0·13 per cent. or so, instead of 0·18 per cent., then sugar would be constantly passed into the urine during the time the blood-sugar was above 0·13 per cent. These periods are represented by the *shaded part in the curves. This is the most* common type of renal glycosuria. Here the urine passed for an hour or two after a meal would contain sugar, but urine passed immediately before the following meal would be sugar-free, for at that time the blood-sugar would be considerably below the 0·13 per cent. threshold. In some cases, however, the threshold is lower than the normal blood-sugar value of 0·1 per cent. In this type of case sugar is constantly passed into the urine, and the condition is virtually the same as that artificially induced by the administration of phloridzin. Here there may be a severe drain *on the carbohydrate stores of the body with the* result that comparatively *large amounts of acetone and diacetic acid may appear in the urine between meals.* Shortly after a starch meal these ketone bodies are much reduced or disappear altogether, to reappear again after some hours.

CHART 1.



Daily variation of blood-sugar in health.

This combination of glycosuria and marked ketosis *naturally suggests that the case is one of ordinary* diabetes, and it requires very great care to ascertain what its true nature really is. Though this severe type of renal glycosuria is not very common, I have actually seen two patients suffering from this condition within the last three months. It is well recognised that reduction of the sugar reserves in the tissues results in marked ketosis in the normal individual, and in these cases of severe renal glycosuria with a very low threshold the amount of sugar lost through the kidneys is so great that the carbohydrate stores in the body are constantly being depleted; indeed, the drain of sugar through the urine is so intense that there is little chance given for any efficient storage, so that many of these patients must always be on the verge of ketosis. Such patients may show no symptoms which could be definitely ascribed to diabetes, but they sometimes feel out of sorts, and under these circumstances the finding of both sugar and ketone bodies in the urine naturally suggests a diagnosis of diabetes.

The figures in the following table were obtained from a case of this kind. *It will be seen that the* effect of the ingestion of glucose on the blood-sugar was exactly what might have been expected in the normal individual, yet this patient was passing sugar at the rate of about 5·6 g. per hour, while the urine at the same time contained a considerable amount of acetone. The effect of the ingested sugar in temporarily getting rid of the acetone is well seen.

---

* Lecture I. appeared in THE LANCET of June 12th.

*Case of Renal Glycosuria with Ketosis.*

Breakfast at 8.30 A.M. 50 g. glucose in 100 c.cm. taken at 12 noon.

| 6 | 5·4 | Pos. (slight). | — | — | — |

The bladder was emptied at 12 noon but no further specimen could be obtained till 1.30. After this the patient was able to pass half-hourly specimens. After two hours acetone disappeared entirely from the urine, to reappear again some hours later. One hour after taking the sugar the respiratory quotient had risen to 1.

While taking ordinary diet this patient's urine always contained from 4 to 5 per cent. sugar along with very considerable amounts of acetone. Indeed, as far as the urine was concerned, there was nothing to distinguish this case from one of typical diabetes. The lack of symptoms taken in conjunction with the normal sugar-tolerance curve and the fact that the taking of sugar removed the acetone bodies all indicated that the condition was one of extreme renal glycosuria. This view was also supported by the fact that sugar taken by mouth raised the R.Q. to 1. The patient was ultimately put on ordinary diet containing a considerable proportion of starch, while some carbohydrate was also given occasionally between meals.

Renal glycosuria requires no treatment; it never does any harm beyond the loss of carbohydrate which results from its presence. General metabolism is usually unaffected, and as far as any damage to health is concerned, the sufferer from this condition may be looked upon as a normal individual. Frequently the question of life insurance arises in connexion with this glycosuria. The general view of the matter now taken by the more progressive companies is that, provided the patient is otherwise healthy, renal glycosuria need not be considered as a disadvantage. Sometimes a lowered renal threshold is present in true diabetes, but this can be determined by the sugar-tolerance test.

## DANGERS OF INSULIN IN RENAL GLYCOSURIA.

The administration of insulin to a patient suffering from renal glycosuria is an exceedingly dangerous proceeding, for even a small dose may result in producing insulin poisoning of a severe type. The reason for this action of insulin is seen when we consider that insulin symptoms are liable to supervene whenever the blood-sugar gets too low. The continual drain of sugar through the kidneys tends very materially to lower the blood-sugar, so that when the effect of insulin is superadded the result is likely to be disastrous.

That the differential diagnosis between *diabetes mellitus* and *glycosuria innocens* may be very difficult is illustrated by a case recently described by Kulcke. His patient suffered from very marked renal glycosuria —so marked indeed that Kulcke's view was that she was suffering from diabetes as well. The administration of 20 units of insulin at once set up serious hypoglycæmia symptoms. From the description of the case given by Kulcke it would seem that the patient was almost exactly of the same type as the patient described above—just a severe case of renal glycosuria.

## SUGAR-TOLERANCE TESTS IN GLYCOSURIA.

In advanced cases of diabetes there is usually no difficulty whatever in arriving at a correct diagnosis. The patient's symptoms at once suggest that diabetes is probably present, and examination of the urine fully substantiates this suspicion. Indeed, in many of these cases the patient gives a description of his symptoms which more nearly approximates to the typical text-book description of diabetes than is the case in almost any other disease. At this stage the disease is in an advanced state, but in the early stage in which glycosuria is the only well-marked symptom a correct diagnosis may be a matter of extreme difficulty. It is most important, however, that the true nature of the glycosuria should be appreciated at this stage, for if it is not, the patient may be quite unnecessarily subjected to a very severe dietetic régime, or, on the other hand, if the condition happens to be really diabetic, the sufferer may be deprived of the value of early treatment.

Though many suggestions have been made as to the best methods for distinguishing diabetes from glycosuria of various kinds, experience amply proves that by far the most useful method we possess at the present time is the sugar-tolerance test. This test is by no means an ideal method, and it has very marked limitations, yet on the whole it generally seems to give us more information as to the nature of the glycosuria than any other method. The principle of this test has been fully described in my former lecture. It consists simply in giving 50 g. of sugar to the patient and estimating the blood-sugar at half-hourly intervals.

### *Different Curves obtained with Sugar-tolerance Test.*

In the normal individual the blood-sugar should return to normal within two to two and a half hours after the ingestion of 50 g. glucose, and should not exceed 0·18 per cent. at any time during the test. Usually, the normal figure is reached in one and a half to two hours; occasionally it may be delayed to three hours especially in elderly people. Generally speaking, if the blood-sugar does not return to normal in two and a half to three hours after taking 50 g. of glucose, there is something wrong with the carbohydrate metabolism. These results are often expressed in the form of a curve.

In the typical diabetic curve the blood-sugar is, of course, generally rather high to begin with, but afterwards the blood-sugar rises considerably above the threshold line and may continue to rise for two or four hours; it returns to the initial value very slowly or not at all, according to the degree of diabetes present. The essential difference between the normal and diabetic curve is that in the former the threshold value of the blood-sugar is not exceeded so that no sugar appears in the urine after the ingestion of sugar, while in the latter the blood-sugar remains high for a considerable period and then tends to come down very slowly. In renal glycosuria the curve is normal, or indeed rather lower than normal, due to the loss of sugar by leakage through the kindeys. There is, however, one type of curve which is peculiar and which I have named the "lag" curve. Here the blood-sugar, which is usually normal to begin with, very soon reaches a point considerably higher than the normal threshold of 0·18 per cent. In its earlier stages it resembles a diabetic case. Very frequently in such a case the blood-sugar may rise to 0·22 or 0·23 in half an hour. Instead, however, of continuing to rise the blood-sugar quickly decreases, so that in one and a half hours or so it regains the normal value. So far as I have been able to judge by watching patients, this curve does not signify any defect in carbohydrate metabolism. Probably all it means is that absorption is exceedingly rapid and that an excess of sugar enters the circulation before the liver storage mechanism gets into action. So far as a diagnosis is concerned, the curve is of no more significance than that of renal glycosuria. The condition is, of course, associated with a certain amount of transient glycosuria.

The following figures are examples of the results obtained by the sugar-tolerance test in various conditions. The blood-sugar was estimated in the usual way before giving sugar and at intervals of half an hour afterwards. The dose of sugar, as in all the results of the test described in this paper, was 50 g. glucose.

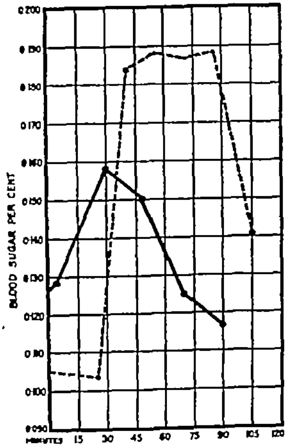
*Some Factors affecting the Sugar-tolerance Curve.*

The sugar-tolerance curve tends to be affected in various diseases. In some conditions it is higher and longer than normal, indicating a diminished ability to deal with carbohydrate, while in others no appreciable rise in the blood-sugar can be detected after 50 g. of sugar have been taken. One of the most important factors in influencing this curve is starvation. Lack of the necessary amount of carbohydrate food results in a tendency to give a high prolonged curve not unlike that found in diabetes. This effect of starvation is well seen in Chart 2. The curve represented by the heavy line is the normal curve given by a healthy subject under normal conditions. The dotted curve was obtained from the same subject after he had starved for 40 hours. The difference in the two curves is very obvious and shows the marked tendency for starvation to produce a curve indicating a lowered sugar tolerance. The same result is produced when a patient's diet is changed from a more or less normal one to a diet consisting largely of protein and fat. The importance of this observation lies in the fact that very frequently when a medical man comes across a case of glycosuria he takes the view that it is best to assume, for the time at any rate, that the case is really diabetic in nature. He, therefore, begins dietetic treatment at once, and later has the case thoroughly investigated to ascertain whether the glycosuria is or is not of diabetic origin. No doubt this is an excellent principle, but it not infrequently happens that a patient sent for examination in order to ascertain the nature of the glycosuria has had his usual diet changed, and has been on a rather low, almost starch-free ration, for several days previously. The result is that such a patient will probably show a high, long-drawn-out curve, something like what might be expected in an early stage of diabetes. Naturally, unless the person making the examination remembers this effect of change of diet, he will be inclined to look upon the case as diabetic, when it really may be nothing of the kind. The difficulty is further complicated by the fact that the change in diet which produces this effect in the sugar curve gives rise, at the same time, to the presence of acetone in the urine. Such a patient then would show glycosuria and acetonuria, and on examination by means of the sugar-tolerance test would probably give a curve somewhat suggestive of diabetes. In spite of all these points so strongly indicating diabetes, the patient might really be suffering from nothing more than renal glycosuria. It is most important, therefore, when carrying out a sugar-tolerance test, to ascertain carefully the immediate previous history of such a patient, particularly with regard to diet. If the diet has been changed recently, and the new diet contains much less starch than he was accustomed to take, then a curve indicating lowered sugar tolerance, even when associated with acetonuria, may be of no significance. These points are of very great clinical importance, for many patients are labelled diabetic after thorough investigation simply because the investigator does not appreciate the above points. The following figures were obtained from a young female patient aged 19, who had been treated for three weeks for diabetes before a test was carried out. When I examined her she was very thin and weak and presented the usual superficial appearances of a diabetic patient. She was on a very low diet, but despite this fact the urine contained a considerable amount of sugar; acetone was also present in large amount. At this time the patient was so weak that she could only walk short distances. The blood-sugar curve gave figures which were much higher than normal, as will be seen from the following results:—

CHART 2.



Sugar-tolerance curve in health (heavy line) and during starvation (interrupted line).

Blood-sugar .. 0·12 .. 0·15 .. 0·16 .. 0·18 .. 0·18 .. 0·16

From a consideration of the curve and the history of the case, together with the fact that the diet was very rigid, the view was taken that this was probably a case of renal glycosuria. The sequel proved this view to be correct. The patient was put on ordinary diet and soon became quite strong and fit. She put on flesh rapidly, and when examined three months later gave the following figures:—

Blood-sugar .. .. 0·12 .. 0·15 .. 0·13 .. 0·09

There was still, of course, considerable glycosuria, but the acetonuria had disappeared.

The contrast between the two results is very marked and indicates the extreme importance of considering the diet of the patient before coming to any definite conclusion. When the acetone present in the urine is dependent on lack of sufficient starch in the diet, or is due to starvation, it frequently happens that the *acetone disappears after sugar has been taken by mouth.* Thus in carrying out the sugar-tolerance test, the first specimen of urine passed may contain much acetone, while another specimen passed two or three hours after the ingestion of the glucose may be acetone-free. When this happens, the inference is that the acetonuria does not indicate diabetes, but is dependent on dietetic factors.

The sugar-tolerance curve is frequently affected in certain well-defined diseases other than diabetes. In some cases the tolerance for sugar is decreased, while in others it is markedly increased. The well-known effect of alcohol and other toxic substances in producing glycosuria is too well known to require discussion here, and the same may be said with regard to local sepsis giving rise to glycosuria. Disturbances of carbohydrate metabolism, apart from diabetes, are found chiefly in lesions of the endocrine glands.

PITUITARY GLAND.

In the fairly common condition affecting young people known as Fröhlich's disease, in which the patient tends to be excessively fat, the blood-sugar curve is often markedly affected. This condition is probably associated with a diminished activity of the gland—a hypopituitarism. In many such cases the curve tends to be more or less flat; the blood-sugar does not rise appreciably even after the ingestion of large amounts of sugar, and the storage mechanism in the liver is apparently exceedingly active. The curve obtained is very like that found after injection of insulin, and it is by no means improbable that the diminution in pituitary secretion results either in the production of larger amounts of insulin, or permits the insulin normally secreted to be more effective *in its action. The antagonism between pituitary* extract and insulin is well recognised, and it may well be that in this type of hypopituitarism, insulin action is more effective than it is normally. In this respect it is interesting to note that, not infrequently, diabetic children who receive insulin become exceedingly fat, and in some cases take on the appearance associated with Fröhlich's disease. In hyperpituitarism sugar tolerance tends to be lowered. Though, in the majority of cases of hypopituitarism, there appears to be an increase in sugar tolerance, yet in some cases the reverse is the case. On the whole, however, diminished secretion of the pituitary gland is associated with increased power to deal with sugar, while in hyperactive states of the gland carbohydrate metabolism is below the normal standard. The following figures, for which I am indebted to Dr. Gardiner-Hill, were obtained from a case of Fröhlich's disease and from a case of acromegaly :—

| | | | | | |
|---|---|---|---|---|---|
| Fröhlich's disease.. | 0·095 | 0·128 | 0·128 | 0·100 | 0·089 |
| •Acromegaly .. .. | 0·362 | 0·388 | 0·474 | 0·392 | 0·412 |

It is interesting to note that after treatment of hypopituitary cases with thyroid and pituitary extracts the blood-sugar curve tends to return to the normal.

### THYROID GLAND.

It is well known that Graves's disease is often associated with glycosuria, and in this disease sugar tolerance is not infrequently markedly diminished. It might be expected, on the other hand, that myxœdema would be associated with an increased sugar tolerance, but, as a matter of fact, the myxœdema curve is very frequently, though not always, a prolonged one, much on the same lines as that obtained in Graves's disease. The average curve, based on examination of a large number of patients, obtained in cases of Graves's disease is as follows. Two results from a case of myxœdema are also given; one represents the blood-sugar before treatment, while the other shows the effect of thyroid medication.

| | | | | | |
|---|---|---|---|---|---|
| Graves's disease average curve .. .. .. .. | 0·113 | 0·180 | 0·188 | 0·165 | 0·140 |
| Myxœdema .. .. .. | 0·100 | 0·193 | 0·181 | 0·182 | 0·180 |
| Same case after thyroid treatment .. .. .. | 0·100 | 0·135 | 0·130 | 0·113 | |

In cretins the sugar-tolerance curve may be low or high; here absorption probably plays an important part. The effect of one year's treatment of a cretin, aged 37, is well shown by the following figures :—

| | | | | |
|---|---|---|---|---|
| Before treatment.. .. | 0·095 | 0·167 | 0·232 | 0·241 |
| After " .. .. | 0·081 | 0·152 | 0·139 | 0·091 |

### EMACIATION AND INANITION.

In many cases of emaciation the sugar-tolerance curve gives a more or less flat line. Sometimes this emaciation is associated with some definite cause, but often no cause whatever can be found. The patient wastes away and gets steadily thinner and weaker, though all the organs appear to be quite sound. Generally, in such a case, various endocrine products are tried, but usually with negative results. There is little doubt that in such patients absorption from the intestine is at fault, and that the flat curve obtained after giving sugar is due to the fact that the sugar is not absorbed. Many of these cases do remarkably well on insulin. The administration of insulin seems to stimulate metabolism with the result that absorption from the intestine improves, and gradually a normal condition is established. In these patients, of course, insulin must be used *very cautiously* and in conjunction with sugar given by mouth. The doses, to begin with at any rate, should always be small. I have seen two patients who were steadily wasting away in spite of all treatment whose lives were apparently saved by stimulating the metabolism by means of insulin. The result of insulin treatment in one of these cases is shown by the following figures. The first line indicates the results of a tolerance test carried out before insulin treatment, while the second line gives the figures obtained after the patient had been on insulin for six weeks.

| | | | | | |
|---|---|---|---|---|---|
| Before insulin.. .. | 0·09 | 0·11 | 0·11 | 0·10 | 0·10 |
| After " .. .. | 0·11 | 0·14 | 0·16 | 0·11 | 0·09 |

This patient, though very emaciated to begin with, got on very well and regained her normal weight after insulin. In some of these cases cautious use of insulin seems to be the only method by which the patient can be helped.

### METABOLISM IN DIABETES.

Since the essential defect in diabetes appears to be a difficulty in burning up the food absorbed, it might be thought that metabolisn would be lower in a diabetic subject than it is in the normal individual. In other words, the natural assumption would be that the amount of heat produced by the diabetic body would be less than that evolved by the healthy body. Strange to say, this does not seem to be the case; the metabolism in the diabetic is just as marked as it is in the healthy individual. Though the diabetic has lost, to a large extent, the power to burn sugar and fat, yet he must be able to burn other substances (his own tissues) with remarkable intensity. Oxidation is apparently quite brisk in the diabetic patient. It is the power to oxidise certain specific substances that is lacking. It would seem as if the defect in the diabetic lies in failure to convert the sugar into some specific substance which is normally oxidised.

### OXIDATION OF FAT IN DIABETES AND ITS BEARING ON DIET.

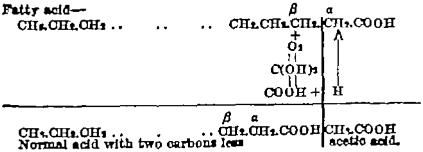
The oxidation of fat is markedly interfered with in diabetes with the result that acetone, diacetic acid, and oxybutyric acid—the so-called *ketone bodies*—appear in the urine. Since fat is a combination of fatty acid with glycerine, it is possible that the glycerine part of fat may act as a sugar in the body, though this is still disputed. The fatty acid is the important part as far as fat metabolism is concerned. In order to understand our present views on fat oxidation it will be necessary to consider very briefly the chemical structure of the fatty acids. All fatty acids consist of chains having the group COOH at one end and the group $CH_3$ at the other. The *simplest* of these acids contains these two groups only; it is therefore $CH_3.COOH$ or acetic acid. All the acids above acetic acid have $CH_2$ groups between the $CH_3$ and COOH. Thus, the 3 carbon acid—propionic acid—is represented by the formula $CH_3.CH_2.COOH$. For each additional carbon in the higher acids there is an extra $CH_2$ group. Now, the normal fatty acids in the body consist of very long chains containing 16 and 18 carbon atoms. They are palmitic and stearic acids. Palmitic acid, for instance, contains 14 $CH_2$ groups in addition to its $CH_3$ and COOH groups and would be represented as follows :—

$$CH_3.CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.$$
$$CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.CH_2.COOH.$$

Now, though these chains are very long, the longest chain ever found as a disintegration product in the diabetic body contains only 4 carbon atoms—i.e., diacetic acid. No intermediate products between this 4 carbon acid and the normal 16 and 18 carbon acids have ever been found in the body. Obviously, therefore, the difficulty in diabetes is to deal with this lower fatty acid. The body can easily break down the long fatty acid chain until an acid with 4 carbon atoms is left, but apparently it cannot oxidise this comparatively simple product. The consequence is that 4 carbon acids appear in the urine in diabetes; these acids are diacetic and oxybutyric. Probably the first to appear is diacetic acid, and from this oxybutyric acid is formed. Certainly the acetone so often found comes from a breakdown of diacetic acid.

### HOW ARE THE FATTY ACIDS OXIDISED?

All the evidence at present available seems to support Knoop's theory of $\beta$ oxidation, or oxidation of the carbon atom second to the COOH group. In chemical language the C atom in the $CH_2$ group next the COOH group is called the $\alpha$ carbon, while the next is the $\beta$ carbon atom. Now, according to Knoop, oxidation of the fatty acid takes place at *the $\beta$ carbon atom. The result is that oxygen is* added on here, giving a COOH group and a free H which is in turn attached to the adjacent $\alpha$ carbon group as represented by the formula.



Fatty acid—
$CH_3.CH_2.CH_2$ .. .. .. $\overset{\beta}{C}H_2.CH_2.CH_2.\overset{\alpha}{C}H_2.COOH$
+
$O_2$
$C(OH)_2$
COOH +
H
$CH_3.CH_2.CH_2$ .. .. $\overset{\beta}{C}H_2.\overset{\alpha}{C}H_2.COOH$
Normal acid with two carbons less
$CH_3.COOH$
acetic acid.

According to this view it will be seen that every acid with an even number of carbon atoms has two carbon groups broken off as acetic acid. The part left is again oxidised in the same way, acetic acid being again formed, and an acid with two fewer carbon atoms left. This goes on until an acid with 4 carbon atoms is arrived at. In the normal body this acid is presumably broken down into two molecules of acetic acid, but the diabetic organism, for some obscure reason, fails to oxidise this 4 carbon acid, with the result that it appears in the urine. It is an extraordinary thing that the diabetic organism can oxidise *with ease all the long changed fatty acids* down to diacetic acid, but entirely fails when it has to deal with this comparatively simple product. If Knoop's view is correct, it is obvious that acetic acid must be very readily oxidised by the diabetic organism, since it does not appear to be excreted in the urine to any appreciable extent. Also, the theory demands that each molecule of fatty acid should furnish only one molecule of the 4 carbon acid. The evidence available seems to support this demand, but it is, nevertheless, uncertain whether, after all, the theory is correct. There is, however, no doubt that the diabetic organism has really lost, to a great extent, its power to deal with the lower 4 carbon acid, while it can apparently *break up the long chain* of palmitic and stearic acids without difficulty. The subject at present constitutes one of the most mysterious problems in biological chemistry. The general explanation given is that the oxidation of the final diacetic acid requires the oxidation of sugar as well. Since starvation will induce the presence of diacetic acid in the urine, it would seem that the old idea that fat can only burn in the "fire of carbohydrates" is based on some element of truth. Apparently, oxidation of fat can go on irrespective of sugar oxidation until diacetic acid or an acid containing 4 carbon atoms is reached, but this acid can only burn when sugar is burnt as well. This view is supported by some experiments of Shaffer, who showed that when sugar was acted on in vitro by hydrogen peroxide, the oxidation that took place resulted in the removal of diacetic acid if the latter was present in the solution. Starting from this test-tube experiment Shaffer carried out many observations on diabetic patients in an endeavour to establish some relationship between the amounts of sugar required to oxidise definite amounts of fat. As a result of this work he came to the conclusion that each molecule of fat required the presence of a molecule of sugar for complete oxidation. If, for the sake of simplicity, we take fat as represented by the chemical body stearic acid $C_{18}H_{36}O_2$, it required one molecule of sugar $C_6H_{12}O_6$ to oxidise this. Since the molecular weight of stearic acid is 284, and that of sugar 180, it follows that 180 parts by weight of sugar should completely oxidise 284 parts by weight of fat. In other words, in order to obtain complete oxidation of fat, the diet should not contain more than 284 parts of fat to 180 parts of sugar, or approximately 1·5 by weight of fat to 1 by weight of sugar.

As the result of this interesting work of Shaffer many investigators carried out experiments on diabetic patients, and in a general way confirmed Shaffer's view, though not all agree that it requires as much as *one molecule of sugar to burn one molecule of fat.* Thus Wilder and his colleagues, as the result of much work on the subject, put forward the view that one molecule of sugar oxidised two molecules of fat. This is now generally accepted more or less, and diets are made up so as to avoid having more than two molecular proportions of fat to one of glucose. This means that the diet should not contain more than three parts by weight of fat to one of glucose. Since oxidation of fat produces ketone bodies, and sugar tends to prevent their appearance in the urine, it is now customary to refer to ketone-producing substances as "ketogenic," and sugar as an "antiketogenic" substance. Most of the recent work *on this subject has been largely carried out in America,* and has certainly tended to emphasise the fact that it is necessary to preserve some definite relationship between the different constituents of the diabetic diet. On the other hand, it is quite uncertain whether there is really any definite molecular relationship between the oxidation of fat and sugar. Indeed, such very wide variations are found in different patients, that it is difficult to imagine that such a definite relationship really holds. It is not impossible that the absence of ketosis, where sufficient sugar is burnt, is largely due to a sparing action of the sugar on the fat. It must be remembered that the whole conception is still but a theory which from some points of view has, perhaps, obtained more importance than is justified by the facts. After all, it was known for many years that adjustment of the diet, particularly with regard to the relative amounts of fat and carbohydrate, was important in order to control acidosis. This was accomplished by a method of trial on the individual patient. In spite of the work that has been done, the only satisfactory method of adjusting diet in diabetes is to ascertain by trial what suits any particular patient best. The above principles are, however, very useful in helping us to arrive more quickly at the diet which will probably suit our patient best.

### INSULIN AND DIABETES.

So *far as the treatment of severe diabetes is concerned* insulin is always indicated, for in such cases diet is seldom successful. It is now generally acknowledged that insulin, when judiciously used, will control any case of uncomplicated diabetes, but the hopes that were sometimes expressed in the early days to the effect that insulin might ultimately cure diabetes have not been borne out by results. There is no evidence that insulin can cure diabetes, though in young growing children its use may result in a very considerable recovery of tolerance. In the adult some intitial increase of tolerance may take place during the earlier stages of insulin administration, but this is never very marked. One of the most important points to remember in regard to insulin is that its effect is considerably diminished when acute infection complicates the diabetes. When a diabetic patient who is on insulin treatment gets an infection of any kind, coma is very likely to intervene, unless the dose of insulin is materially increased. Neglect of this fact has resulted in many unnecessary deaths.

There are very few contra-indications to the use of insulin, but it should never be given if its use can *possibly be avoided in cardiac conditions with suggestions of angina pectoris.* In patients with ordinary valvular lesions insulin seems to cause no trouble, but several cases of sudden death after insulin injection have occurred in patients who had previously shown some evidence of anginal features, however slight. This danger is associated with the hypoglycæmia which to some slight degree is probably present at some time or other in every patient whose insulin dose is sufficient for his needs. With the exception of this variety of cardiac disease, I do not think there is any other contra-indication to the use of insulin in any case of diabetes.

### MODE OF ACTION OF INSULIN.

As already shown, sugar disappears from the blood as the result of oxidation or conversion into another substance—glycogen—in the tissues. Since the administration of insulin increases the rate at which sugar disappears from the organism, it might be expected that insulin either increases oxidation of sugar or results in the formation of more glycogen. In other words, that the administration of insulin simply increases the normal processes of carbohydrate metabolism. For the last few years a very considerable amount of work has been carried out with a view to ascertaining how insulin really acts, but so far little light has been thrown on the problem. Quite recently, however, Dale and his colleagues have shown that in the decerebrated eviscerated animal the use of insulin results in the disappearance of sugar from the circulating fluid, and that this decrease of sugar is proportional to the increase of glycogen *plus the sugar destroyed* by oxidation. It must be admitted that these experiments were carried out on animals under conditions far removed from the normal, but the results have gone further to show the manner in which insulin really acts than any work that has been so far published. Strange as it may seem, the isolation of insulin has thrown practically no light on the large subject of carbohydrate metabolism.

# NON-SPECIFIC PROTEIN INJECTIONS IN CHRONIC ARTHRITIS,

## WITH AN ANALYSIS OF FIFTY CASES.*

BY W. YEOMAN, M.B., L.R.C.P. LOND.,
HONORARY PHYSICIAN, ROYAL BATH HOSPITAL, HARROGATE.

THE treatment of arthritis by the injection of a foreign protein into the system has been practised for some years, many observers claiming that this treatment has an advantage over all others. A large number of preparations have been used, vaccines, colloidal metals, peptones, horse serum, and milk being the most commonly employed.

### *Résumé of the Literature.*

The treatment was first tried by Ichikawa in 1912, who, by the intravenous injection of an antityphoid vaccine in cases of typhoid fever, reduced his mortality in this disease from 30 to 11 per cent., and terminated the disease after the first or second injection. To Kraus, however, is due the discovery that the benefit was not produced by a specific reaction, for he found that he obtained similar results with a *B. coli* vaccine. The conception of the non-specific reaction dates, however, further back than that, for Jobling and Petersen [1] quote Mathes as having demonstrated in 1895 that the tuberculin reaction could be equally well produced if deutero-albumose were used. Between this date and 1912 there was no serious attempt to investigate the treatment of disease by a non-specific immunity response. Since 1912, however, it has been tried in most diseases, whether acute or chronic, and there is voluminous literature on the subject in America and Germany. In England the chief publications come from Gow and Auld, and in Scotland from Campbell.

Auld,[2] working with colloidal metals in cases of septic infection, found little or no benefit result until he used a preparation which he discovered later had been preserved with "veal peptone." In agreement with most other observers, he found that little benefit was effected unless a sharp febrile reaction was obtained. The veal peptone preparation gave this reaction, and he concluded that it was the peptone element which produced it. He considers, however, that the typhoid vaccine is a more effective agent.

Gow [3] confined his observations to acute diseases and summarised the type of case suitable for non-specific therapy as follows:—

1. Infective disease in which the causal organism is unknown or not certainly determined—e.g., rheumatic fever and acute toxic arthritis.
2. Infective disease in which the causal organism is known, but autogenous vaccine therapy is of little value—e.g., gonorrhœal arthritis.
3. Infective disease in which the causal organism is known and vaccine is given for both its specific and shock effect—e.g., typhoid, paratyphoid, and coliform infections of the urinary tract.
4. Chronic disorders of unknown ætiology—e.g., psoriasis,[4] pemphigus, and lupus erythematosus.[4]

He quotes a case of pyelonephritis which he treated by intravenous injections of an autogenous *B. coli* vaccine, and after four injections the urine remained free from *B. coli.* Using intravenous injections of specific organisms in acute disease—e.g., septicæmia, pneumonia, influenza, and cystitis—Gow [5] also found that the coliform bacilli were the only type that evoked a striking leucocytosis.

Other investigators soon turned their attention to the treatment of arthritis by this new remedy, and in 1916 Miller and Lusk [6] published the first series of treated cases. They used typhoid vaccine and preparations of proteose. In 10 cases of "acute articular rheumatism," after one injection of 150 millions of typhoid vaccine, three were cured, and the result was permanent. In the remaining seven it was necessary to give three to four daily injections before obtaining a permanent result. In a further six cases of subacute type of from three to nine months' duration, benefit was derived in all cases. They report the occurrence of relapses, especially in cases complicated by endocarditis or pericarditis. The results in cases of chronic gonorrhœal arthritis were striking, but were more resistant to treatment, one patient receiving 13 injections.

Smith [7] reported the injection of horse serum in cases of gonorrhœal arthritis, with very satisfactory results. He attributed the success to anaphylactic shock. Cecil [8] records the effect of this method of treatment in 40 cases of acute arthritis, made up as follows: rheumatic fever 26, acute toxic arthritis 7, gonorrhœal arthritis 7. Typhoid vaccine was used and the usual dose was between 40 and 80 millions. Three patients, by an error in technique, were given 400 to 500 millions with hardly any added severity in the reaction or difference in the therapeutic result. The average number of injections per patient was 1·8 in the fever cases, 1·5 in the toxic, and 5·5 in the gonorrhœal.

In the cases of rheumatic fever 40 per cent. completely recovered without the use of salicylates; the remaining 60 per cent. required salicylates to relieve the muscular pains which persisted. In only three cases was no benefit obtained. The cases of gonorrhœal arthritis received little benefit by the treatment. He concludes that the febrile response is the most important factor in producing relief of symptoms, and that salicylic acid is still the most effective drug in rheumatic fever, and that vaccines should only be employed after the failure of salicylates.

---

* Read before the Harrogate Medical Society on March 18th, 1926.

Snyder and Ramirez,[9] in a series of 70 cases confined to the more obstinate cases of chronic arthritis, reported only 8·6 per cent. cures, and all in patients who had symptoms for less than two years. They used typhoid bacilli and secondary proteoses prepared from milk, and consider the secondary proteoses give as satisfactory clinical results and are less toxic and more pleasant for the patient. Snyder,[10] using stock typhoid vaccine, reports 60 per cent. cures in the acute cases by one injection, and 30 per cent. in from one to five injections, while 10 per cent. show no improvement. In the subacute cases—i.e., less than one year duration and with no ankylosis—25 per cent. showed considerable and 25 per cent. slight improvement. In the chronic cases of from one to ten years' duration there was merely a moderate increase in the mobility of the joints. Betz [11] reports on a series of 50 cases. The acute cases, as a rule, cleared up after the first injection, but some required three. Middleton [12] used *B. coli* or typhoid vaccine in ten cases, and states that in the early cases the disease was arrested, and in the chronic ones there was improvement in the general condition and relief of pain.

The most complete British record of the treatment of arthritis by this method that I can find is by Stockman and Campbell,[13] who report on 70 cases which they followed up for from 1 to 3½ years. Typhoid vaccine was used, and the dose varied from 125 to 200 millions. Detoxicated vaccine gave no beneficial results. In the series 58 derived immediate benefit and in 40 of these the benefit was permanent. Of the remainder 2 could not be traced and 16 relapsed. In some of the latter the injections were stopped early owing to rapid improvement. Of the 12 who did not improve, 4 were of very long standing though the disease was inactive; 1 gave only a slight reaction, 7 reacted well, but the infection remained active. Campbell considers that the maximum benefit is obtained in that type of case in which the disease starts in a more acute form with constitutional disturbance and a fairly rapid involvement of many joints. With an insidious onset of the disease and few joints affected at any one time, the patient generally retained some disability and was more liable to relapse.

On the continent less work has been published than in America, but mention should be made of a series of 600 cases by Paul [14] who administered vaccine by scarification. Attention was drawn to this work in THE LANCET [15] with the suggestion that as the claims are very large—65 per cent. cured and 95 per cent. improved—the treatment should be investigated "by those who are dissatisfied with their own results in the big group of fibrositic maladies." On the continent the chief preparations used for this purpose are sterilised milk, peptone, and, in Germany, an extract of cartilage prepared according to the instruction of Heilner [16] called "Sanarthrit."

Nolf[17] concludes that intravenous injections of peptone made salicylate treatment more efficacious in certain obstinate cases of rheumatic polyarthritis, and enhanced its value in the treatment of a group of acute arthritic cases which had hitherto proved refractory. He stresses the importance that care should be exercised in giving the peptone, that the quality should be of the best and prepared under aseptic conditions. He advises the injection of adrenalin to prevent as far as possible the "shock" effects of the peptone injection.

*Theories of Non-specific Therapy.*

Many theories have been advanced to place this somewhat empirical treatment on a scientific basis, but space forbids me to go into them in detail. To those, however, who are interested I would commend a book on "Protein Therapy and Non-Specific Resistance," by W. F. Peterson. He considers that the organism is stimulated to greater production of either specific substances, antibacterial in character, or that the general resistance to intoxication is increased. Perhaps the most reasoned and feasible theory is that advanced by Herrmann,[18] who concludes that the injection of foreign proteins serves as a stimulus for the liberation of specific antibodies in animals in which previously injected antigen was unable to do so. This theory was recently investigated by Ling,[19] who injected various foreign proteins into normal human beings. He found that serum antibodies including bacteriolysins for *Bacillus typhosus* and *Staphylococcus aureus* were "shed" into the circulation within 24 hours by the injection of foreign proteins. He found that the most effective agents to produce this as well as the reactive leucocytosis were the bacterial proteins, typhoid vaccine, and market milk—the latter being better than Certified Milk which contained less total organisms.

It has also been found that antibodies which have gradually disappeared after an infection or following immunisation artificially produced, again returned to the serum after any procedure that increased the body temperature, whether by increasing the external temperature, by influencing the thermal centre of the brain, or by injecting pyrogenic drugs. This tends to show that hyperthermia has a direct stimulating effect on the previously formed antibodies.

*Records of Fifty Cases.*

My own series consists of 50 cases treated at the Royal Bath Hospital, Harrogate. I have purposely excluded private cases so that the type of case, the diet, and the treatment might be as far as possible uniform. Of the 50 cases, 18 were men and 32 women, their ages varying from 19 to 66 years, the average being 40. There was no outstanding occupational cause for the arthritis. Of the men, 5 were miners and 4 clerks, and of the women 10 were married. As to the locality, 23 came from the West Riding of Yorkshire, and of these 9 came from Leeds. Durham produced 9 and the remainder came from different localities scattered over England and Scotland.

In common with other observers I found it difficult to classify the cases. I have used, as far as possible, the classification detailed by Pringle and Miller in THE LANCET.[20] All the cases were polyarticular and of the subacute or chronic type. The average duration of the disease for the series was three years; the shortest was two months, following an attack of influenza, and the longest 20 years.

| | |
|---|---|
| Infective— | |
| (*a*) Associated with septic focus .. .. | 41 |
| (*b*) Unknown origin .. .. .. .. | 1 |
| (*c*) Associated with zymotic disease .. .. | 2 |
| Metabolic .. .. .. .. .. .. | 5 |
| Periarticular fibrositis .. .. .. .. | 1 |
| | 50 |

In each case I used the typhoid paratyphoid vaccine prepared in the laboratories of St. Mary's Hospital and retailed by Messrs. Parke, Davis and Co. This vaccine is made up in the approximate proportions of 2 parts of *B. typhosus* to 1 part each of *B. paratyphosus* A and B.

*Technique*.—I use a 10 c.cm. Record syringe with a needle of medium bore, and, after drawing up the required dosage of vaccine, dilute this with normal saline solution to 5 c.cm. A suitable vein in the antecubital fossa is chosen, and the injection given slowly.

*Dosage*.—In hospital practice I usually start with a dose of 100 million total organisms and increase each subsequent dose by 100 millions, as each injection establishes a certain amount of tolerance. In private practice, however, I find it best to start with 50 millions, for the reaction to 100 millions in private patients is often severe and prolonged, lasting two days and, in some cases, even three days. I am unable to give any explanation for this. Cecil[8] recommends 30 to 100 millions, Campbell[13] 125 to 200 millions. Miller and Lusk[5] gave 150 millions and then reduced the dose to 75 millions. Cowie[21] seldom gives a dose less than 600 millions, and has given this dose in children with no untoward result. He, however, considers a good average to be 100 millions with a maximum of 500 millions.

*Frequency of Injections.*—In the majority of cases I allow four days to elapse between the injections. In the more chronic cases this allows the patient to recover from the reaction, enjoy the improvement in his condition, and enables him to face the ordeal of the next injection. In America the injections are frequently given daily, but those cases were acute rheumatic fever, and one or two injections sufficed to cure the condition. Cowie [22] points out that as there is no negative phase as far as the antibody content of the blood is concerned he sees no reason why injections should not be given daily. However, as the reaction is so great, he advises that it is best to allow a day to intervene.

### *Anaphylaxis.*

I see no reason to fear any anaphylactic reaction, for in one of my cases a second course was started within six months of the first; in another two within nine months, and in a case in private I gave the doses at monthly intervals. In no case was there any resemblance to an anaphylactic reaction. Gow,[5] however, advises an intradermal test to see if the patient is sensitised.

### *Reaction.*

Within a short time of the injection a feeling of chill starts which usually progresses to a shivering attack, and in most cases becomes a true rigor. This takes place any time from a quarter to one and a half hours after the injection. A period of warmth supervenes and the temperature begins to rise, usually reaching its maximum about four hours after the injection. The highest temperature recorded in my series was 104·2° F. Cecil [8] has recorded a temperature of 107°, which is the highest on record. As I pointed out before, it is impossible to predict what the temperature will do at the first injection. It may not reach its maximum for 12 hours, and in these cases it may be 36 to 48 hours before it eventually returns to normal. When the temperature is going up the patient feels acutely miserable; there may be nausea to the point of vomiting, headache, backache, and generalised pains in all the affected joints. Even joints which have been quiescent for some time may show signs of renewed activity. When the maximum is reached the temperature gradually falls, and with the fall in temperature is associated profuse perspiration. I think this perspiration is an important factor, for I notice that the patients who derive the greatest benefit have the most profuse perspiration. With the fall in temperature all the unpleasant sensations are replaced by a delightful feeling of euphoria. The swelling of joints subsides, pains disappear, and joints which were previously locked can be moved painlessly and freely. This stage lasts from 24 to 48 hours, and then the pains gradually begin to return, but never to the same extent, and each injection causes the return of symptoms to be less marked. After each injection the temperature returns to normal within 24 hours. Next day the patient is able to have 40 minutes general massage and get up after it.

### *White Cell Count.*

White cell counts were done on each patient during the first and last reactions as a routine. These findings corroborate those of other observers—namely, that there is a leucopenia corresponding to the rigor, then a sharp leucocytosis following the rise of temperature, and a return to the previous level, or, in some cases, below it in 24 to 48 hours. A differential count shows an absolute decrease in the polymorphonuclear neutrophiles during the leucopenia, followed by a large increase, and a relative and absolute decrease in the lymphocytes. Very high figures are recorded for the leucocytosis. Campbell [13] mentions 40,000 as the maximum in his series. Miller and Lusk [4] state that a count of 52,000 occurs in acute arthritis and 25,000 in the subacute cases. The highest count recorded in my series was 27,000, which occurred five hours after the injection.

### *Blood Pressure.*

Petersen quotes Scully as recording a slight increase in the blood pressure during the chill, then a decline of 10–25 mm. Hg for six to eight hours, returning to normal in 24 hours. One or two cases developed herpes.

### *Dangers and Contra-indications.*

In America deaths have been recorded on account of the size of the dose given, but Snyder and Ramirez [9] state that these cases were so ill they ought to have been considered as not suitable. Petersen states that delirium is set up in cases of typhoid, typhus, and erysipelas, and delirium tremens in alcoholics. Two of my cases became rather excited and confused for a short time on two occasions, but they did not cause any anxiety and completed their course of injections without any further complications. There were no other complications in any of the patients. Campbell [13] reports a case of hæmaturia in one case in a patient who had albuminuria prior to the injection. It should be remembered that the vaccine is suspended in a solution of dilute carbolic acid and it may have been the acid which caused the hæmaturia. Two of my cases had albuminuria before the injections, and they did not develop hæmaturia or any symptoms referable to the kidneys. Snyder [10] reports five cases of "gastric hæmorrhage" and eventually these cases showed the best results. He also does not consider a high blood pressure or heart disease well-compensated contra-indications. I agree with him in this, for one of my patients had a systolic blood pressure of 190 mm. Hg and gave a very good result, and another case with a well-compensated lesion of the mitral valve showed no ill-effects and did well. Petersen reports that in an old tuberculous or syphilitic lesion the reaction is liable to cause a flare up of symptoms.

### *Balneological Treatment in Association with Injections.*

All my cases had balneological treatment in the interval between the injections. Every day, except the day of the injection and occasionally the next day, they had a pint of strong sulphur water before breakfast and half a pint of magnesia water at 11 A.M. On the day the temperature was normal—usually the day following the injection—they had 40 minutes dry general massage. Special attention was given to the joints which were stiff or showed fibrous ankylosis, and attempts were made to break down adhesions during this stage. For the following three days local treatment, such as paraffin wax, radiant heat, and Berthollet followed in some cases by ionisation, were given to the joints most severely affected.

A natural question to ask is how do these results compare with those in which no injections have been given? Unfortunately, a definite statistical answer cannot be given; we do not possess a registrar or house physician at the hospital, and the honorary staff has as yet been unable to do a detailed "follow up" of all cases. I hope that this omission will be rectified at an early date.

### *Results.*

Of the 50 cases, after an average stay of four weeks in the hospital, 44 were discharged as definitely improved, and 6 as no worse but no better. I have sent to each patient a long questionnaire which has been answered in all cases. This shows that 34 have maintained their improvement and in some cases advanced to a definite cure. The longest period since discharge is one and a half years and the shortest four weeks. Of the 44 who were discharged improved, 12 have not improved, 5 having become worse than when they left hospital, and 7 remaining as they were on discharge. Of the 6 who were discharged in statu quo, 2 have improved and speak of themselves as cured, 3 have become worse than when they left hospital, and 1 has remained in the state in which she was on discharge—i.e., 8 are worse than they were on discharge and 8 are in statu quo. A few details about these 16 cases are of interest. Taking, first of all, the 8 who are worse, 4 of them had a definite focus of sepsis which has not been removed; 2 of them have a condition of achlorhydria, in one amounting to a true achylia. One was given only two injections, and as there was no clinical improvement they were stopped. One remained well for eight months and then relapsed, and writes that he feels a further course would cure him. Of the 8 who remained in statu quo, 3 had a focus of infection which has not been removed. Two were of the menopause type. One had only two injections and another only three, owing to no clinical improvement. One improved for six months and then relapsed. In my questionnaire I asked if there was a relapse for a short time after leaving hospital, and the answer was in the affirmative in 20 cases. Of these, 17 recovered from the relapse and improved.

### *Clinical Records.*

CASE 1.—R. S., No. 35. Admitted April 9th, 1925. Single woman aged 30. Teacher of music (piano). History: In February, 1925, had an attack of influenza, and one month after recovery started with pain and swelling in right foot. This quickly spread till all joints became painful and swollen. Influenza six years previously, otherwise no other illnesses.

*Condition on Admission.*—The left elbow and shoulder and the right foot were painful and stiff. There was much swelling of both wrists and these joints were hot. Most of the interphalangeal joints were involved, so that she was unable to play the piano. A routine examination revealed no focus of infection. Intravenous injections were commenced on April 10th, 1925, and given every fifth day for five injections. I started with 100 million total organisms and increased the dose by 100 millions each time. Each injection except the last was followed by a rigor, the temperature went sharply up, the highest recorded being 103·4° F. This was followed by a most profuse perspiration and the improvement in the joint condition was dramatic, for the day after the first injection the inflammation and swelling had disappeared. She was discharged on May 6th, 1925, having gained 1¼ lb. in weight, feeling very well, with free and painless movements of all joints, and able to play the piano. She writes (February, 1926) that she still keeps free from symptoms and has been working since discharge.

CASE 2.—E. M., No. 47. Admitted May 28th, 1925. Married woman aged 25. No children. History: At the age of 15 started with pain and swelling of fingers. Gradually spread to knees, ankles, wrists, and shoulders. Was treated at Buxton, but gradually got worse. Tonsils removed 1923 and improved after this, but had a bad relapse after an attack of influenza in March, 1925. No previous illness. Periods regular.

*Condition on Admission.*—Well nourished; pale; tongue furred; bowels open with medicine; teeth sound; throat clean; heart, no disease. Joints: Fibrous ankylosis and swelling both wrists with only very slight movement. Creaking both shoulders and right elbow. Creaking and pain in both knees. Creaking in both ankles.

*Laboratory Reports.*—Fæces: Strept. non-hæm., *Strept. fæcalis* (c), *B. coli* (in order of predominance). Urine: *Staph. albus*, scant growth. No other abnormalities.

*Treatment.*—One pint sulphur water and ½ pint magnesia water daily. Berthollet steam bath to arms and legs. Five intravenous injections of T.A.B., starting with 100 millions and working up to 500 millions. On discharge, June 24th, 1925, there was a marked improvement in the general health. The knees were free from pain with only slight creaking. There was no pain or swelling of the wrists, and more movement in the left wrist. An autogenous vaccine was prepared from the culture of the fæces and mixed with stock strains. She was given weekly injections of this for seven months. She had a slight relapse after leaving the hospital, but soon picked up, and rapidly lost all symptoms, except in the wrists, which still remained very stiff. She was readmitted Jan. 28th, 1926, with a view to further injections to see if the wrists could be made freely movable. Treatment as before except that paraffin wax baths to the hands were substituted for the Berthollet. Five intravenous injections of T.A.B. were again given. This case is interesting as corroborating the findings of Pringle and Miller[10] in their paper on the glucose tolerance curve. At the commencement of treatment there was an appreciable intolerance to carbohydrates and, at the end, though the "Lag" element was still present, there was marked improvement.

On discharge on Feb. 24th, 1926, the general health was again much improved, and the wrist movements were definitely improved, and no other joints showed symptoms. After discharge there was a slight relapse as the knees which had been quiescent for seven months became swollen again, but by March 9th she had quite recovered, and the wrists were still more flexible.

Since this paper was written this patient has steadily improved, and except for slight limitation of movement at the wrist, has no symptoms of a "rheumatic" character.

This case shows how the disease tends to continue even though all sources of infection have been dealt with as far as possible.

CASE 3.—A. W., No. 46. Single woman aged 36. School teacher. Admitted July 30th, 1925.

*History.*—Started in 1918 with pains in hands, which quickly spread to most joints. She had an extensive treatment in Buxton and again in Harrogate in 1923. She improved slightly after each, but relapsed again in February, 1924, and then had a prolonged course of electrical treatment, but became much worse again in March, 1925. She had kept at her work with long periods of sick leave till this last attack, which finally incapacitated her.

*Condition on Admission.*—General condition, fair; tongue furred; bowels constipated; teeth sound; throat clean. Joints: Fibrous ankylosis with only very slight movement both wrists, and great swelling of all metacarpo-phalangeal joints both hands. Creaking both knees. Pain on shoulder movements both sides.

*Laboratory Reports.*—Fæces: *Strept. fæcalis* (a), *B. coli*. Urine: *Staph. albus*.

*Treatment.*—1 pint sulphur water and ½ pint magnesia water daily. Berthollet steam bath to legs. Paraffin wax to hands. Radiant heat to shoulders. Five intravenous injections of T.A.B. were given, starting with 100 millions and working up to 500 millions.

*Result.*—After the first injection the swelling round the joints was much less, but there was no relief from pain. After the third injection all the joint movements were free and painless. A letter received a month after her departure states: "I feel I have got a new lease of life. I have worked at top pressure every day since discharge." This has been maintained to date.

This was a most intractable case of a steadily progressing infective process which advanced in spite of all treatment until the injections were given.

CASE 4.—T. G. B., No. 15. Married man aged 50. Occupation, a grocer. Admitted May 22nd, 1924. Weight (dressed), 9 st. 1½ lb.

*History.*—Pains started suddenly in right wrist in December, 1923, then went to ankle and finally to most joints. He was in bed three weeks.

*Condition on Admission.*—General condition very poor, practically helpless, wasted, and pale. Tongue furred. Bowels open regularly. Teeth, one remaining; rest have been recently extracted—not more than two at a time—for gross sepsis. Pulse 138. No bruit. Apex beat, normal site. Joints: Creaking both shoulders with limited movement in left. Left knee hot and greatly swollen; creaking and pain on movement. Both ankles hot and painful. Man could only get about in a wheeled chair, and could hardly do anything for himself.

*Laboratory Reports.*—Fæces: *Strept. fæcalis* (a), *B. coli*, *Strept. viridans* (in order of predominance). Urine: Sterile. Test-meal: Achlorhydria with small secretion of HCl in stomach. Very rapid emptying.

*Treatment.*—1 pint of strong sulphur water and ½ pint magnesia water daily. Berthollet steam bath to both knees and ionisation to left knee and both ankles. Acid. hyd. dil. 1 drachm three times a day with meals. Seven injections of vaccine prepared from stools and mixed with stock strains. Ran a septic type of temperature during the whole of his time in hospital.

*Result.*—Weight 9 st. 4¼ lb., increase 2¾ lb. Still very helpless—unable to walk. General condition improved.

Readmitted: Oct. 9th, 1924. Weight, 8 st. 8¼ lb., loss of 10 lb.

*Condition on Admission.*—General condition showed a slight improvement. He did not look so toxic, but his joints were worse and he was still helpless. Joints: Creaking and limitation of movement left shoulder. Both knees are now hot and swollen, and there is pain and creaking on movement with much limitation of range. Pain and limitation of movement right ankle, and creaking and swelling of left ankle.

*Laboratory Reports.*—Fæces: *Strept. fæcalis* (a), *B. coli*. Urine: Sterile, *Strept. fæcalis* (c) (in order of predominance). Test-meal: Achlorhydria. Normal chloride curve. Neutralisation effect. Blood count: Simple anæmia, moderate degree.

*Treatment.*—1 pint strong sulphur water and ½ pint magnesia water daily. Berthollet and ionisation to knees. Acid. hyd. dil. 1 drachm as before. Seven intravenous injections of T.A.B. vaccine, starting Oct. 13th, 1924, with 100 millions and working up to 500 millions. There was a sharp reaction after each injection, usually accompanied by a rigor.

*Result.*—Discharged Nov. 19th, 1924. Weight 8 st. 12¼ lb., increase of 4 lb. From being helpless and requiring to be wheeled about in a chair, he got on to crutches, and, on leaving, could get about with the help of two sticks. His temperature, which was raised on admission, continued until after the fourth injection, after which it remained normal except during the reactions after the other three injections. He writes (February, 1926): "I am pleased to tell you I am practically myself again. I can follow my work quite nicely."

Space has not allowed me to give the cases in full detail, but I think the abridged details are clear enough to demonstrate the valuable aid these injections give in the treatment of arthritis.

### *Summary.*

1. In the intravenous injection of T.A.B. vaccine we have a therapeutic agent which is capable of producing improvement in a short space of time in between 80 and 90 per cent. of all types of arthritis, and this improvement is maintained in between 50 and 60 per cent.

2. The types which respond best are the acute and subacute where the disease is confined to the peri-articular tissues—in these cases permanent benefit is assured in over 90 per cent. of the cases. Where the joints themselves are affected definite improvement occurs with arrest of the disease, but naturally bony changes cannot be altered.

3. If all possible foci of infection have not been removed the injections do not arrest the disease and the patient will relapse.

4. Though the reactions are severe the contra-indications are few—disease of the myocardium, gross kidney disease, chronic alcoholism, tuberculosis and syphilis being the chief.

5. The most desirable reaction is that in which there is a rigor, sharp rise of temperature, quick fall, and profuse perspiration, and dosage should be regulated to produce this.

6. In view of the proved ability of these injections to cut short an attack of rheumatic fever, I would plead for an extended trial of this treatment in the hope that much invalidity from heart disease might be prevented.

7. The cases which do not do well are those of the menopause group of the chronic villous type, and those showing *achylia.*

In conclusion, I should like to express my sincere thanks to my colleagues on the staff of the hospital for their encouragement and advice, to Mr. S. Linfoot, who did all the white cell counts, and to the nursing staff, who so willingly undertook the extra nursing entailed.

# THE PATHOLOGICAL ACTION OF LIGHT UPON THE EYE.

BY W. STEWART DUKE-ELDER, B.Sc.,
M.D. ST. AND., F.R.C.S. ENG.,
PLIMMER RESEARCH FELLOW IN PATHOLOGY.

*(From the National Institute of Medical Research and the Ultra-Violet Clinic, Royal London Ophthalmic Hospital.)*

## PART II.* (*continued*).—ACTION UPON THE LENS: THEORY OF THE GENESIS OF CATARACT.

### 4. *The Experimental Production of Cataract.*

(1) *Long Wave-lengths.*—Cataract due to electrical oscillation has been produced in animals by Hess (1888) and Kiribuchi (1900), using the discharge from a Leyden jar. The electric effect is very probably complicated by concussion effects, whose influence in the coagulation of proteins has already been referred to (mechanical shock and agitation).

(2) *Infra-red Waves.*—Isolated heat rays readily produce a lenticular opacity, a result which has been obtained by several experimenters—Richen (1913), Vogt (1918), Grinella (1924), Muller (1924), Kranz (1925). Using concentrated light from a carbon arc the writer, in conjunction with Leonard Hill, has produced an opaque disc-like opacity on the anterior surface of the lens in five minutes in rabbits; with less intense exposures a diffuse opacity occurs throughout the lens; with still less a posterior opacity develops after some days.

(3) *Visible Rays.*—Opacity has been produced by visible light (concentrated sunlight with the infra-red and ultra-violet excluded) by Werneck (1834), Czerny (1867), Deutschmann (1882), Langenbeck (1903), and Herzog (1904).

(4) *Ultra-violet Rays.*—Under experimental conditions opacity is difficult to obtain owing to the difficulty of getting a sufficient amount of short-waved radiation through the anterior eye; further, the lens proteins appear to be more stable under these radiations than most others. Several observers have, therefore, reported negative results. Using intense radiation, it has, however, been produced by Widmark (1898) to a marked degree, and by Verhoeff and Bell (1916) to a slight degree. The latter observers, moreover, showed that when a lens thus exposed remained clinically transparent, on keeping it for 48 hours in normal saline a definite haze developed confined to the pupillary area. The isolated lens also, on exposure to ultra-violet, if suspended in physiological saline, turns similarly opaque (Chalupecky, 1913; Soret, 1893), an observation confirmed by the writer; the opacity is a faint hazy one, which, on keeping in saline, develops much more intensely than unradiated controls. While complete precipitation is thus obtained only with difficulty, the work of Burge (1916) and Adams (1925) already mentioned shows that the first stages of the process are readily inaugurated. The most innocuous spectral region would appear to be the border-line between the visibles and the ultra-violet (Trümpy, 1925), since here both thermic and abiotic effects are at a minimum.

(5) *Short Wave-lengths.*—Radium has been found to produce cataract experimentally in animals (*Birch-Hirschfeld, 1904–08; Alphonse, 1909*), in the fœtus in utero (Hippel, 1907), and clinically in man (Salus, 1925; Ascher, 1925; and others); while X rays have the same action, as has been demonstrated by experiment in animals (Birch-Hirschfeld, 1904; Tribondeau and Belley, 1907), in the fœtus (Stock, 1907; Herzan, 1907), and has been reported as occurring clinically after intensive therapeutic doses (Paton, 1909; Williams, 1920, and others).

(6) *Sensitisers.*—Sensitisers act in vivo in the same way as they do in a photographic plate; they so modify the substance with which they become

---

* Part III. will appear in a subsequent issue of THE LANCET.

associated that it reacts photochemically to long wave-lengths which ordinarily would produce an inappreciable effect. Thus when an animal is injected with hæmatoporphyrin visible rays produce the same effects as ultra-violet, and, while remaining normal if kept in the dark, if it is placed in sunlight the animal dies in a few hours. Howell (1924) has recorded the formation of cataract in animals so sensitised and exposed to daylight. Apparently, therefore, lenticular opacity can be formed by the action of visible light on sensitised protein. If this finding is substantiated it forms a powerful argument in favour of the possibility of the occurrence of the same reaction, though more slowly, by ultra-violet light. It is indeed possible that a process of continuous photosensitisation may play a part in the production of cataract clinically.

(7) *Salt Concentration and Osmosis.*—Heubel showed (1880) that the injection of hypotonic solutions into the eye made the lens opaque, and that similar intravenous injections produced a like result; further, in frogs, if the injection be pushed rapidly, that the lens remains clear, then, if the animal is immersed in water, opacity quickly develops. It therefore appears to occur on osmotic dilution, and not on concentration—an inflow of water into the lens. The opposite process of concentration of the aqueous, which was the original theory of the ætiology of cataract advanced by Panas (1894) and accepted by Leber (1903), is unrealisable in effective degree in vivo.

### 6. *The Clinical Occurrence of Cataract.*

(1) *Cataract due to Electricity; Electric Cataract; Lightning Cataract.*—It has long been recognised that cataract can readily follow the actual passage of an electric current through or near the eye. The photophthalmic symptoms and the heat effects on the surface which follow exposure to the short-circuiting of a high-tension current, or a lightning flash, have been dealt with in the previous article, but although the infra-red and ultra-violet rays are present in quantity, it is beyond doubt that the formation of cataract is largely due to electro-chemical action, to which must be added concussion effects.

(2) *Cataract due (probably largely) to Heat; Occupational Cataract.*—Wenzel (1808) was the first to note that "les personnes, qui approchent beaucoup le feu, éprouvent un desséchement et une opacité de la cristalline." Since then a very large amount of speculation has centred round the fact that in certain industries where the workmen are exposed to high degrees of heat the occurrence of cataract has been found to be prevalent. Meyhofer (1888) first directed attention to this in glass-blowers, and, although some have questioned it, its prevalence and its right to be considered as an occupational disease was established by Leggo in a Home Office report (1907). While by no means always so, the lesion is usually a typical well-defined disc-like opacity situated in the posterior pole of the lens (Parsons, 1913). A somewhat similar condition has been noted in iron-workers (Crilland, 1913), tin-workers (Healy, 1921), chain-workers (Roberts, 1921), and gold-smelters (Brinton, 1913).

The emission spectrum from molten glass was examined by Crookes (1914), who found that in the ultra-violet it extended down only to 3310 A.U. on prolonged exposures, while the rays in the short infra-red were extremely powerful; he therefore concluded that the ultra-violet were to be exonerated and that the condition was due to heat waves. Schanz and Stockhausen (1910), however, found that, although the spectrum did not extend far into the ultra-violet, yet the short waves were present in high intensity; probably the spectrum varies with the metals used. Moreover, when we consider that the lens absorbs rays up to 4000, that the exposure lasts with intermissions for years, and that the worker, bending over a tank, looks at a source of maximum extensity involving a high energy concentration in the lens, it would seem unsafe to conclude that the mischief is entirely due to the infra-red. Further, the fact that workers in some of the other trades mentioned where ultra-violet is absent seem to be affected less *frequently* points to the probability that while heat is apparently the main factor, the long ultra-violet may also have a not inconsiderable effect. The theory at present generally accepted is that suggested by Parsons (1913) and supported by Hartridge and Hill (1910), that the main factor in the ætiology is malnutrition or irregularly varying nutrition due to changes in the composition of the aqueous or to the liberation of toxins by the action of heat waves falling on the iris and ciliary body. The cataract is, therefore, either a complicated cataract consequent on a chronic, mild inflammation of the ciliary body, or a degenerative change induced by periodic variations in the nutrition of the lens. The only evidence of such a mild iridic involvement that has ever been brought forward is the demonstration of hæmolysins in the aqueous after raying, which, according to Römer (1903), occurs only in iritis and after paracentesis. Römer's statement is, however, wrong, for more recent and refined methods have demonstrated the presence of hæmolysins in the normal aqueous of highly immunised animals in small amounts. The action of heat rays is non-specific; in the present case, as always, the initial action is to dilate the capillaries, its subsequent action to induce congestion, stasis, hæmorrhages, and perivascular leucocytic infiltration; there is no evidence of a specific iritis, and no toxin will presumably be liberated until, as in other parts of the body, the lesion is pushed to the extremity of an actual burn involving tissue destruction—an unlikely event under the circumstances, even allowing for the absorption by the pigment. When the capillaries are dilated their permeability is increased, and substances of colloid aggregation are allowed through their walls in larger quantity than normally. Thus albumin, globulin, and fibrin appear in the aqueous, which may, therefore, coagulate and give the appearance of a fibrinous exudate. Hæmolysin is, or behaves as if it were, a colloid (Bechold, 1907; Eisler, 1923), related to, or associated with, globulin (Homer, 1920; Ruppell, 1923); its presence in the aqueous in quantity is merely an index of capillary dilatation by any agency whatever. Clinically, there is no evidence of any pathological change in the iris of the men affected. The fact that the opacity is a posterior polar one has been cited as analogous to a complicated cataract following a chronic cyclitis; its occurrence here can amply be accounted for by the concentration of radiant energy by refraction through the cornea and the lens, by reflection from the posterior surface of the lens, by the absence of convection currents in this region, and by the large accumulation of radiant energy here when emitted from a source subtending a large solid angle. In any case, the comparison is an extremely superficial one depending merely upon site, for the intimate structure of glass-blowers' cataract as revealed by the slit-lamp is widely different from that of complicated cataract (Schnyder, 1920).

A toxic origin being unlikely, we are left with a physiological change: malnutrition due to changes in the aqueous. A considerable amount of recent evidence and as yet unpublished and uncompleted researches by the writer are tending to show that in all probability the aqueous is within biological limits a dialysate of the blood-serum, virtually stagnant, with only a minimal circulation due to transudation and osmosis through the capillaries, and to pressure changes induced by muscle movements. Apart from its being highly oxygenated, it probably plays the part only of a vehicle in the nutrition of the lens, whose metabolism is presumably regulated in very large measure by the efficiency of its own autoxidation system. If this is the case, the only change that capillary dilatation will bring about will be the alteration of its colloid-crystalloid content in accordance with the requirements of a Donnan's equilibrium—i.e., an increase in the colloid content and a decrease in the crystalloids, with a total very slight increase in osmotic pressure. This will have a minimal effect on the nutrition of the lens, and any effect the small osmotic variation will have on the fluid traffic of the latter will be a tendency for water to flow out of it, an effect the reverse of that required to induce opacity.

In contradistinction to this, cataract is readily produced by heat; the short time interval we have seen from a consideration of the chemistry of the changes is no objection to the two conditions being similar in nature, while it throws out of court any indirect action through the ciliary body. This is further emphasised by the fact that opacity can be produced in the same way in albino rabbits (Vogt, 1925) where there is no pigment in the iris to absorb large quantities of heat. Further, in Italian glass-workers, who work very near to the furnace, corneal opacity is common (Critchett, 1913); it seems only reasonable to attribute the same effect to the same cause, and this is obviously the direct result of the incident radiant energy. The fact that the cornea does not always turn opaque before or with the lens is explained by the greater concentration of energy in the latter when the radiating source subtends a large solid angle; in the case of a small source, as is used experimentally, it frequently does become opaque first. Further, physiological repair of submaximal damage is much less evident in the lens, and the cornea is more able to cope successfully with a noxious agent acting over a long period of time. At the same time, however, while the direct action of the incident energy upon the lens itself probably is the fundamental factor in the ætiology, the other is almost certainly of importance secondarily in bringing about the conditions necessary for the flocculation of the proteins already rendered labile by the denaturing action of heat and light; and the increased "permeability" of the capsule which will probably follow exposure will further assist in allowing abnormal fluid traffic.

(3) *Cataract due (probably largely) to Long Ultra-violet Light. Senile Cataract.*—There is a large amount of evidence which may be brought forward to correlate the incidence of senile cataract with the radiant energy from the sun, and to assume with Hertel and Henker (1910) that it is axiomatic that daylight by a process of adaptation has become innocuous, is probably too sanguine, and certainly unscientific. It seems beyond doubt that cataract is more common in India than it is in Europe, and statistics show that it matures earlier—20 years (Hirschberg, 1898), 10 years (Snell, 1907), while the frequent occurrence of black pigmentation due to melanin in the lenses of natives which are otherwise clear has already been mentioned, and its significance as indicating a first stage in the development of opacity has been indicated. According to Walter (1919) the same thing holds in America, cataract becoming more common as we approach the equator. Daland (1917) remarks upon its frequency in the Arctic regions, where the sunlight is especially rich in ultra-violet, which is reflected from the surface of the snow with dazzling brilliancy. Schwitzer (1895), Grosz (1895), and Hirschberg (1898), comparing workers in the fields with those living in the towns in Germany and Austria, found the incidence of cataract much greater in the former who are exposed all day to the sun. Further, Ascher (1917), over a series of uniocular cases found industrially, states that the side of incidence can be traced definitely to the side of constant brilliant illumination while at work; while with even more refinement of localisation, Handman (1909) states that 81 per cent. and Greene (1908) that 95 per cent. of Indian cataracts commence in the lower quadrant of the lens, where the incident light falls more directly.

The radiation from the sun may be taken as that of a black-hot body at 5000° C. absolute; its spectrum ranges from the infra-red down to 2910 A.U. under the most favourable conditions (Cornu, 1878), the maximum energy density being about the blue-green, 4700–5000 A.U. (Abbot, 1906). The infra-red forms only a small portion of the energy output, and the greater part of it is absorbed by the water vapour of the atmosphere, which may be taken to average a layer of water 1·5 mm. thick; of those which are left the lens absorbs only 3·8 per cent. (Luckiesh, 1913), the main bulk passing to the retina. Any thermal effect, therefore, will be associated with the visible rays rather than the infra-red, and in the lens with its high transparency to these wave-lengths their effect must be small. On the other hand, there will be a large energy absorption in the lower visibles and long ultra-violet between 4000 A.U. and 3000, especially in the adult and senile lens, and this energy is potentially capable of inducing pathological change. No distinction can be drawn between the effect of the infra-red, the visibles, and the longer ultra-violet on the ground of heat radiation, and all attempts at differentiating their action in this sense is scientifically unsound. Abiotic action for the usual intensities ends at the upper limit of about 3100 A.U.; Coblentz and Fulton (1925) state that it may, under favourable conditions, be attained up to 3600; all appreciable action above that is thermic in nature. The large portion of the solar energy absorbed by the lens can, therefore, produce both thermic and abiotic effects.

It is highly improbable that the solar energy induces direct coagulation. The changes are almost certainly of the much more subtle nature we have already discussed—a diminution of the glutathione content lessening very gradually the efficiency of the autoxidation system, and a change of the proteins into a more labile state so that they are more easily coagulated by other factors. Sooner or later the actual occurrence of cataract is determined by changes in hydrogen-ion concentration, in salt content, in osmotic conditions, or in nutritional disturbances.

The objection that has always been raised to the theory of the direct action of sunlight is that in 93 per cent. of cases (Magnus, 1890) senile cataract begins in the periphery where the lens is protected by the iris, and not in the pupillary aperture where the light falls. Apart from the fact that a predilection to the inferior segment has been recognised, this criticism is readily answered. In a slow process of the nature we are considering (diminution of glutathione, &c.) the action will tend to be felt uniformly throughout the lens; further, the greater portion of the shorter waves which are dispersed are reflected at right angles, and will thus affect the periphery towards which they will be concentrated by internal reflection, and where many of them will be absorbed. In this region are situated the younger and more actively growing fibres which will call for the highest efficiency of the autoxidation system to maintain their more active metabolism. These will, therefore, be the first to be affected by its deterioration. At the periphery, moreover, it has been shown by the injection of dyes that most of the fluid interchange into the lens occurs, and the effects of any change in the nature of the ocular fluids will therefore be first seen here.

The hypothesis was first advanced by Peters (1900) that senile cataract was due to disturbed nutrition owing to pathological change in the ciliary epithelium. Van der Hoeve suggested in 1912 and later (1918) elaborated the theory that the light, which was dispersed in its passage through the lens, on falling upon the ciliary body, would cause minute damage of such a nature that could not be detected clinically or microscopically, and that this would result in impaired nutrition and consequent degeneration of the lens. It is difficult, however, to believe that the ciliary body of all cataractous persons is diseased, and, moreover, the same arguments apply to the present case as we have considered in the discussion of occupational cataract. In addition, the factor of physiological repair to slight damage in a tissue with the metabolic activity of the ciliary body must be taken into account. The fact that 65 per cent. of persons between 51 and 60 years (Horlacher, 1918) and 96 per cent. of those above 60 (Barth, 1914) have lenticular opacities detectable by the slit-lamp would seem to be more probably explained by the known and experimentally proved action of radiant energy on the autoxidation system of the lens and the stability of its colloid system.

(4) *Cataract due to very short Wave-lengths.*—The occurrence of cataract due to gamma rays is rare, presumably owing to the rarity of sufficient exposures. Ascher (1925) and Salus (1925) report several cases where treatment was given for eye diseases by the prolonged application of radium. The opacity usually develops some time later in the posterior cortex. Opacity of the cornea occurs as well. Williams (1920) reports a case where the evidence points to a cataract developing bilaterally in a woman of 40 years as being due to a course of 60 treatments of X rays to her face.

(5) *Other Forms of Cataract; Diabetic Cataract.*—Two conditions are met with in diabetes; in the first place senile cataract is comparatively common and appears at a relatively early age, while in the second a characteristic form of cataract peculiar to the disease occurs, although with much greater rarity. The differential diagnosis can best be made by the slit-lamp, and on its basis Schnyder (1923) found one case of true diabetic cataract in 50 cases of senile cataract occurring in diabetic subjects. The main factor which, in all probability, determines the high incidence and early occurrence of senile cataract is the fact already considered that both sugar and acetone in small quantities sensitise proteins, including the lens proteins, to the denaturing action of light, while, in addition to this, the diabetic state, by subjecting *the lens to an osmotic deforming force and abnormal* fluid traffic, induces the condition still more readily, accelerates its rate of development, and tends to alter its type. *True diabetic cataract is largely* determined by the latter factor.

The writer (1925) has already suggested that in the rising sugar concentration of *diabetes*, provided the available water reserve is maintained, the osmotic pressure of the aqueous tends to decrease; fluid therefore tends to flow in to the lens. If the process is a relatively mild one the lens swells and is deformed, its curvature and refractive power are increased, and the eye tends to become myopic; if, however, the change is greater and the inflow of fluid more rapid, actual droplets are formed under the capsule, and the transparency of the lens is impaired by the irregular dispersion of light at the interfaces between the two media of different refractive indices—aqueous and lens fibres. These fluid vacuoles have been noted in cases of acute diabetic myopia by Lundsgaard (1910) and *Strickler* (1911), and they are readily seen in cases of typical diabetic cataract (Schnyder). A "cataract" is thus formed with great rapidity. *Conversely, with a fall in sugar* concentration, a reverse osmotic flow is set up, fluid flows out of the lens, and in the first case the eye becomes of normal or hypermetropic *refraction*; *in the second, provided further* organic changes have not taken place, the fluid droplets will disappear, and the cataract clears up, as has been observed in diabetes by Nettleship (1885), Nicholson (1923), Joslin (1924), and Fischer (1924). This abnormal fluid traffic and the formation of actual droplets between the *lens fibres* will in time induce actual opacity of the latter, a process no doubt largely aided in part by the actual strain of mechanical deformation tending to *protein denaturation* (a seemingly slight force, but at the same time possibly comparable to the coagulation occurring on the surface of a soap bubble or *between the phases* of two immiscible fluids), in part by changes in the hydrogen-ion concentration and salt content, and in part by the upset of the autoxidation system. *This last* might well affect the soluble β-krystalline and the glutathione, which, being diffusible, might be carried away through the capsule whose "permeability" is almost certain to suffer in the general malnutrition that accompanies diabetes.

A peculiarly *oedematous state of the ciliary* epithelium in diabetes has been described by Kamocki (1887) and corroborated by Zentmayer (1913), which, being peculiar to this disease, was *attributed* by its discoverer to a specific "cytotoxin"—an explanation hitherto accepted—and was supposed to be a causal *agent in the incidence of diabetic cataract*, acting, as the infra-red rays were said to act in occupational cataract, by inducing lenticular malnutrition indirectly through changes in the aqueous. Since, however, all signs of inflammation are absent and the appearances described are evidently passive, the more likely explanation would appear to be that they are osmotic in origin—a purely physical process of œdema, running parallel with, and having no causal relation to, similar processes occurring in the lens itself.

The clinical characteristics of this form of cataract indicate the importance of this osmotic process in its origin. It always occurs when the sugar concentration is high, and usually when the patient is fairly well—i.e., when he has sufficient fluid reserve. It is practically always bilateral (54 out of 56 cases, Zeller, 1899), and the change starts immediately under the capsule. *It frequently occurs in young subjects*—11 months (Major and Curran, 1925), 5 years (Frey, 1887), 7 years (Schnyder, 1923); it comes on rapidly *and matures quickly, often in a few days*—4 days (Scheffels, 1898), 11 days (Neuburgers, 1893)—and it seldom requires more than a few weeks. With the *slit-lamp the symmetrical opacity in the subcapsular* region is in the early stage seen to be made up of discrete drops of fluid of diameter 0·04 to 0·1 mm. (Schnyder, 1923), larger at the anterior pole, often confluent at the posterior, while the more superficial lens fibres are separated by larger spindle-shaped fluid lacunæ.

The *Cataract of Cholera* is probably to be associated with a similar process. It is said to be due to the abstraction of water from the lens due to the general dehydration (Fuchs), but the opposite process, as in other forms of cataract, is probably at work. In this disease the bowel mucosa is disorganised and allows the passage of material from the blood in the order, first, water and salts, later, organic substances and proteins. This preferential early loss of the dialysable and osmotically active constituents, while rendering the blood more viscous, will make it in the osmotic sense more dilute, and if the fluid volume is at all kept up, water will tend to flow into the lens, inducing opacity as in diabetes.

*Complicated Cataract.*—The determining factors in the formation of complicated cataract are probably *malnutrition and the influence of toxins, acting directly* on the lens substance, or indirectly by altering the permeability of the capsule. It occurs typically in *chronic, slow inflammations, and its localisation to the* posterior cortex in the majority of cases is to be correlated with the fact that here the capsule, being thinnest (*Ulrich, 1893*), *permits of diffusion* more readily than elsewhere, and that here the membrane surrounding the vitreous is firmly attached to it; a slow degenerative change will involve shrinkage both of the lens and of the vitreous, and thus, subjected to the double pull of two shrinking bodies at this point, disorganisation will be hastened by the separation of the fibres and detachment of the capsule allowing the ready accumulation of fluid. Moreover, in the supply of toxic materials, the central hyaloid lymph tract may exert a localising influence (Healy, 1921). The work of Burge (1916), showing the marked influence of calcium salts in the *coagulation of lens proteins* by ultra-violet light is to be associated with the occurrence of cataract in conditions as tetany, myotonia, and aparathyroidea, whether induced experimentally (Hiroishi, 1924) or met with clinically.

Anterior polar cataract, due to approximation of the cornea to the lens capsule, and posterior polar cataract, due to persistence of the hyaloid artery, are not to be considered in the same category. Neither is lamellar cataract, wherein the opacity is due to a number of globule-like vacuoles which are the remains of degenerated or undeveloped fibre cells, a developmental change which is to be correlated with similar hypoplastic changes in the teeth and the skeletal and cutaneous tissues, the result of a general constitutional disturbance.

### *Conclusion.*

The thesis advanced, therefore, is that the primary cause of cataract generally is probably to be associated with the direct action of incident radiant energy of any wave-length on the lens, increasing the lability of its colloidal system and deranging the autoxidation system upon which its metabolism depends. This renders its proteins more prone to coagulation by changes in the hydrogen-ion concentration (which also affects the autoxidation system directly), changes in the salt content, osmotic changes determined locally by the action of radiant energy on the lens capsule or by general metabolic disturbances, and by possible continuous photosensitisation. To these must be added the influence of more subtle factors inseparable from the economy of so complex a physico-chemical mechanism as is living matter; but in the present state of our knowledge it seems most profitable and fertile to try to elucidate these processes by reducing them as far as is possible to the known laws of chemistry and physics, instead of taking refuge behind these meaningless terms so frequently used in pathological thought—malnutrition, degeneration, and toxic action.

It must not be imagined that a complete theory is here elaborated, but rather a tentative hypothesis is offered which touches merely the fringe of the matter. Much of the work which has been referred to requires corroboration; much more requires to be done. The experimental work which has been mentioned will be detailed and elaborated at a later date. The publication of these observations at this early stage is merely an endeavour to stimulate interest in a fascinating problem and to point out the lines along which the writer thinks it might most reasonably be approached.

# A SIMPLIFIED TECHNIQUE FOR BLOOD TRANSFUSION BY THE KIMPTON-BROWN METHOD.

BY W. B. GABRIEL, M.S. LOND., F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON, ST. MARK'S HOSPITAL; LATE CANCER AND SURGICAL REGISTRAR, MIDDLESEX HOSPITAL.

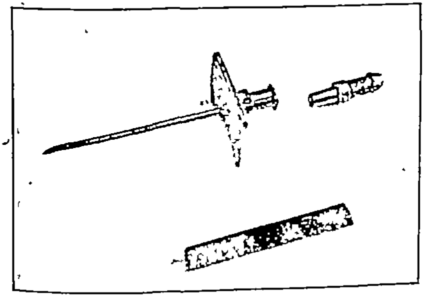
AT the present time the citrate methods of blood transfusion seem to be generally in favour, but where it is possible to bring the donor and patient together my preference is still for whole blood transfusion by the Kimpton-Brown tube. One practical disadvantage in using the Kimpton tube has been the necessity for cutting down on the donor's vein. Many professional donors, or donors not related to the patient, object to having an incision made which needs sutures and subsequent dressings.

In this article I wish to describe briefly a simple and efficient method for filling a Kimpton tube through a needle. As long ago as 1910 Vincent[1] described such a method, using a modified Kimpton tube which had the delivery tip ground so as to make an air-tight connexion with a special needle. He advocated coating the needle with paraffin wax by heating it in a dish of melted paraffin, and after removal the lumen of the needle was maintained by blowing a current of air through it while cooling.

### *Technique.*

The technique which I have employed with success in a series of cases is indicated by the accompanying illustrations. The needle is the Kaliski[2] pattern, gauge 15, with a metal connecting piece and a short length of rubber tubing (size 9, 1¼ in. long) which completes the junction with the Kimpton tube (Fig. 1). A 500 c.cm. Kimpton tube is sterilised by boiling, and a film of paraffin wax is deposited in it from an ethereal solution in the ordinary way. The needle, connecting piece, and rubber tubing are prepared by boiling; it is not necessary to paraffin them. The apparatus is put together in such a way that the end of the nozzle of the Kimpton tube just touches the metal coupler, so that the rubber tubing is practically not in contact with the flowing stream of blood (Fig. 2).

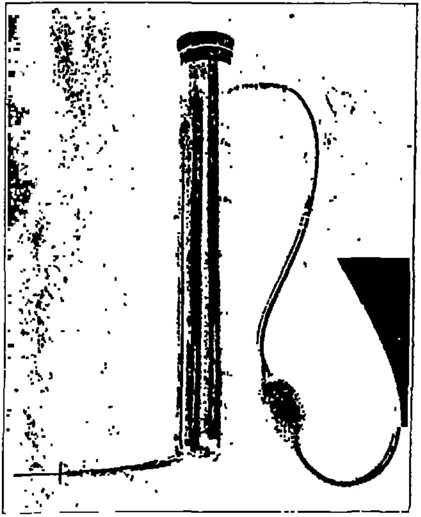
FIG. 1.



The Kaliski needle, connecting piece, and the short length of rubber tubing for making the junction with the Kimpton tube.

When collecting blood from the donor an assistant supports the tube and follows the movements of the operator in order to give him as much freedom as possible in manipulating the needle. A tourniquet is placed round the arm of the donor, and after injecting a few drops of novocaine solution a small nick is made in the skin over the selected vein. The needle is passed into the vein towards the wrist until blood is seen to flow freely into the tube. The suction end of a Higginson's syringe (marked by a piece of tape or bandage) is connected to the Kimpton tube and helps the inflowing blood.

FIG. 2.



The apparatus fitted together ready for collecting blood.

As a rule I pour a small quantity of sodium citrate solution, 3·8 per cent., into the Kimpton tube previous to puncturing the vein. The citrate is pushed up as a layer about half an inch deep on top of the column of blood and enables the whole amount of blood eventually to be given to the patient without risk of blowing air into the vein. If it is desired to fill a second tube it is easy to do so without removing the needle, the metal couplers making it a simple matter to disconnect the full tube and join up the new one. If only 500 c.cm. of blood is required the tourniquet is loosened, and the needle is withdrawn from the donor's vein. An assistant applies digital pressure over the vein to prevent a hæmatoma forming. The rubber tubing with the needle is then rapidly slipped off the Kimpton tube, and a swab soaked in 3·8 per cent. sodium citrate is held over the nozzle until it is passed into the recipient's vein which has previously been prepared, with mosquito forceps marking the edges of the vein. The Higginson's syringe is now reversed in order to expel the blood.

It is necessary in all cases to cut down on the recipient's vein. In difficult cases where the recipients have very small veins there is often considerable anxiety in introducing the nozzle of the Kimpton tube. In such cases it might prove advantageous to

incise the vein and tie in a Kaliski needle just before the tube is ready to be taken from the donor. One could then make a metal to metal junction between the full tube of blood and the recipient; there could never be any difficulty about this.

This method of filling a Kimpton tube by means of a needle is applicable to any case where the donor has the veins of the average healthy adult male. As a rule the tube fills just as quickly as when it is inserted directly into the vein. Where the donor's veins are small and indefinite it is advisable to cut down on the vein and fill the tube directly in the ordinary way.

I have used this method of blood transfusion in a considerable number of cases in the last 15 months, and can strongly recommend it. I obtained the needles here illustrated from Messrs. T. G. Hartz, of Toronto, where I was fortunate enough to see the Kaliski needle employed so skilfully in the syringe method of blood transfusion by the surgical staffs of the General Hospital and the Hospital for Sick Children.

# Clinical and Laboratory Notes.

## AN UNUSUAL CASE OF ACUTE ABDOMINAL EMERGENCY.

BY O. W. ROBERTS, M.D., B.S. LOND., F.R.C.S. ENG.,
ASSISTANT MEDICAL SUPERINTENDENT, ST. GILES' HOSPITAL, S.E.

THE following case of acute abdominal emergency, which belongs to a class of rare occurrence in the practice of a London hospital, is of unusual interest from a surgical point of view.

L. O. H., a frail boy aged 6 years, was admitted on Jan. 16th, 1926, with abdominal pain. The history given was that five days previously the boy was playing on a ladder in a garden when he slipped and fell a few feet, injuring the upper part of the right thigh; shortly afterwards he vomited and complained of abdominal pain. He was put to bed and three days later had recovered sufficiently to be allowed to get up; then, however, the abdominal pain returned and two days later his doctor ordered his admission to hospital. On clinical examination there was a small abrasion about 2 inches below the inner end of Poupart's ligament on the right side; the lower half of the abdomen showed no respiratory movements, and the right side was tender and rigid. Clinically the condition appeared to be due to an appendix abscess.

An anæsthetic was administered and on palpation, prior to incision, an indefinite lump could be felt nearer the mid-line than would be expected from an ordinary appendix abscess. By a right paramedian incision a quantity of free purulent fluid was found, and the small intestine was seen to be distended. On investigation of the cause of the distension a hard, irregular body was discovered passing across the right iliac fossa and penetrating the root of the mesentery; when it was manipulated out of the wound it proved to be a twig of a tree, which must have been driven into the abdominal cavity at the time of the fall. This twig had pierced the femoral ring, the parietal peritoneum, and the root of the mesentery, and had come to rest alongside the second part of the duodenum. Round the twig there was an abscess, containing thick, creamy pus and walled by the tissues of the iliac fossa and by coils of small intestine. About 6 inches of gut near the terminal part of the ileum was in a condition of doubtful viability, but the patient's state did not allow of resection. A large drainage-tube was inserted into the abscess cavity and the abdomen closed. The track in the thigh was opened up for additional drainage, and as a precaution against possible secondary hæmorrhage from the femoral vessels a piece of ribbon gauze was passed up the femoral ring.

An injection of antitetanus serum was given and the boy made an uninterrupted recovery.

The points of interest in this case are: 1. The unusual path taken by the foreign body. 2. The remarkable escape of the femoral and iliac vessels from injury. 3. The healing by first intention of the path taken by the foreign body. 4. The delay in onset of acute abdominal symptoms. 5. The uncomplicated recovery.

## SERIOUS HÆMORRHAGE FOLLOWING OPENING OF PERITONSILLAR ABSCESS.

BY NORMAN PATTERSON, M.B., CH.B. EDIN., F.R.C.S. ENG.,
SURGEON TO THE THROAT, NOSE AND EAR DEPARTMENT, LONDON HOSPITAL, ETC.

THIS complication seems to be sufficiently uncommon to be worth reporting. Ligature of the external carotid appeared to be the only means of saving the patient's life.

Woman, aged 31, married. Four years ago attended Stratford Hospital for menorrhagia; bleeding continued for three weeks. History of a sore-throat for ten days accompanied by swelling on the right side of the neck. The swelling was diagnosed by her doctor as quinsy and was incised and pus evacuated. On the following day the quinsy was again incised and the day after the wound was opened up with forceps. Considerable bleeding followed (six days prior to admission) and it continued until admission. When seen at 5 A.M. on Jan. 5th, 1926, the patient was pale, lips colourless, skin cold and clammy, temperature 98° F., pulse 120. Much swelling was present in the right peritonsillar region. There were two vertical incisions a quarter of an inch long on the anterior surface of the swelling; from the outer one blood was oozing and the pharynx was full of bright blood. The condition improved, but at 11 A.M. the hæmorrhage started again. At 12 noon I saw the case and decided to tie the external carotid. The operation was rendered extremely difficult by the glandular enlargement and inflammatory condition of the neck, by the fact that the bifurcation of the common carotid was situated behind the angle of the jaw about 2 inches above the usual site, and by finding a regular plexus of large veins over the carotid sheath. On account of the friable nature of the tissues some of the ligatures would not hold and the patient was sent back to bed with three pairs of Spencer Wells forceps controlling the bleeding. These were removed on the fifth day. The wound in the neck, which was very septic, took a long time to heal.

Eventually the patient made a good recovery.

## A CASE OF GANGRENE OF THE NOSE DUE TO DIABETES MELLITUS.

BY K. ARDESHIR, M.R.C.S. ENG.

FROM the inadequate facilities for reference at my disposal, I am only aware of three cases of gangrene of the nose in diabetic subjects, described by Bowers, and quoted by MacLean in the "Medical Annual" for 1925.

An Indian female child, aged 8, was brought to me from a neighbouring village on Jan. 19th, 1926, for a rapidly growing boil on the nose. The history given was that it started as a small pimple some four days back.

On examination I found destruction of the ala nasi on the right side; the tissues round about looked definitely gangrenous. A first glance suggested erysipelas, but the rose-red rash was conspicuously absent. It was unlike anything I had seen before. It certainly did not suggest syphilitic origin. The child was evidently ill and very much emaciated, temperature 99·5° F., pulse 103, respiration 29. On further examination I noticed dermatitis of both hands, tongue foul, mouth very septic. I could squeeze out pus from both tonsils.

Urine examination showed: Reaction acid, sp. gr. 1030. No albumin. No casts. 215 c.cm. of urine was found to contain 4·2 g. of sugar. Both diacetic acid and acetone were present.

Local treatment: I removed the slough with a sharp scissors without any anæsthetic. The affected region was cleansed with normal saline, dried, and a dry dressing applied. The dressing was renewed frequently. The mouth was kept thoroughly clean and a saline purgative was given.

Having no facilities for examining sugar in blood, I administered 5 units of insulin subcutaneously; a similar dose was given the same evening. Next day 10 units had to be given. On the third morning the urine was found to be sugar-free after a total dose of 20 units. On the first day nothing but coffee and plenty of fluid was given; later on she was put on a restricted diabetic diet, and was ordered complete rest. After a week the wound showed signs of healing, and on Feb. 6th it healed up completely. 45 units of insulin had to be given during the 10 days she was under my care. The mother refused to transfer the child to a local hospital, thinking it was completely cured, and returned to her village.

On my return from leave I induced the mother with difficulty to bring the child to me on March 19th. The affected region then looked quite healthy, but for the loss of the alar cartilage; 310 c.cm. of urine was found to contain 0 0 g. of sugar. The general condition of the child seemed to have been fairly well maintained.

The interesting points in the case are: 1. The diabetic gangrene of nose in a child. 2. Rapid recovery under insulin. 3. The possibility of use of insulin in private practice without having facilities for examination of blood-sugar. 4. Difficulty of keeping in touch with patients in India to observe effects of after-treatment. 5. Absence of any provision for the supply of insulin in India free of charge to the poorest patients.

Mhow, Central India.

## TWO CASES OF HORSE-POX.

BY F. W. MARSHALL GREAVES, M.B., CH B. LEEDS, D P.H.,
INSTRUCTOR IN VACCINATION, LEEDS UNIVERSITY.

IT will be remembered that Jenner (1749–1823) found that horse-pox, at that time confounded with "grease," was conveyed by the hands of the servants attending to the infected horses to the udders and teats of the cows, and that the milkers were in turn affected on their abraded hands and contracted cow-pox. Cow-pox was originally classed as "natural" or "casual" according to whether the infection of the disease was acquired by the cow in a natural way, as opposed to direct transference of infection from cow to cow by unintentional inoculation by the milkers.

In 1800 Lupton, of Thame, pointed out that the disease of the horse communicable to the cow and known as "grease" was not really grease but a disease analogous to cow-pox and known as "scratchy heel." In the same year a veterinary surgeon of the name of Tanner had produced a vaccine vesicle by rubbing material from a horse affected with grease on to an accidental sore on a cow. Loy, of Pickering, in the following year subdivided the condition in the horse into two forms, acute and chronic, the former being the only condition he recognised as capable of affecting the cow. The condition was unrecognised in France until 1860, and in 1863 two well-defined outbreaks occurred near Toulouse and were investigated by the French Government.

It has been pointed out that, in the past, epidemics of cow-pox have been associated, sometimes indirectly, with previous or concurrent small-pox in the country, and in the epidemics of cow-pox investigated by the Local Government Board in 1887, and subsequent years until 1910, horses and cows were affected at the same time.

Considering that horse- and cow-pox are said to be almost non-existent in this country, the following two cases, which occurred in the outskirts of an industrial area, appear worthy of note:—

In March, 1914, a farrier, aged 50, was seen on account of sores on the hands and arms which went through the vesicular and pustular stages and later showed scarring. There was considerable general disturbance with swelling and pain of the axillary glands on each side, and the condition cleared up in about 19 days. Attempts at vaccination a month afterwards were unsuccessful. In February, 1924, his son, a shoeing-smith, aged 28, was seen with a similar eruption on the hands, arms, face, and chest. The disposition of the rash in the latter area corresponded to the opening of the shirt, and it is possible that the man had further inoculated himself by scratching this part. He recollected that he had had a horse in with an offensive eruption, particularly of the hind legs, but he was unable afterwards to identify the particular animal. There was very little constitutional disturbance and the condition cleared up in 17 days with very little marking, possibly owing to active antiseptic measures. Tincture of iodine effected the quickest alleviation of the condition. A small white scar, however, remains on the face between the eyebrows as a result of the infection, but the scars on the hands and arms are now almost impossible to find. He had been vaccinated in the Army in 1914 but not very successfully as only one small smooth mark, less than a quarter of a square inch in size, shows as the result. The vaccination marks of infancy are of good size and denote a successful result.

In April this year I suggested to him that he should be vaccinated in order to see whether or not he was immune. Four good-sized areas were accordingly scarified and a lymph of known potency rubbed well in. The condition never went beyond the papular stage, aborting on the fourth evening; it must, however, I think, be classed as a positive reaction. It is a matter of regret that the case was not proceeded with on the line of inoculation, transference to the rabbit, &c., but this was not possible at the time. It is an interesting speculation that the so-called "safe" routes over the desert in the early and Middle Ages (by "safe" I mean free from disease in general and small-pox in particular) owed their safety to the inoculation of the camel drivers and attendants with some form of camel-pox, thus rendering them immune to small-pox.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF OBSTETRICS.

A MEETING of this Section was held on May 28th. In the absence of the President, Sir WILLIAM SMYLY took the chair.

*Annual Report of the Coombe Lying-in Hospital.*

Dr. LOUIS CASSIDY, the Master of the Coombe Lying-in Hospital, read the annual report of this Hospital for 1925. He said that the total number of admissions for the year ending Dec. 31st, 1925, was 934, an increase of 186 on the previous year. Eight maternal deaths occurred during the year, a percentage of 0·85, and the number of cases of maternal morbidity was 42, a percentage of 4·5, and an average of 1 case in 22. This showed a big reduction on the previous year's morbidity. The tables were striking, for they showed 24 cases of morbidity in which no vaginal examination had been made, no laceration of the perineum had taken place, and there had been no operative interference. A rise of temperature had occurred 12 times amongst the operative cases, of which two were breech delivery by Smellie's method, one was internal version, three were craniotomy, and six forceps cases. In four other cases rise of temperature was caused by extra-genital infection. Twenty-five cases were examined before labour set in to determine what organisms were present in the vagina and whether they had any bearing on the puerperium. None of the cases had any puerperal rise of temperature, although four showed pure culture of Döderlein's bacillus and 18 showed a mixed growth, including streptococci and *B. coli*. Three cases only had no vaginal bacilli and the flora in these consisted chiefly of streptococci and vast numbers of coccoid forms. This examination seemed to throw very little light on the problem of the cause of morbidity in the 21 cases mentioned, and it was thought that more promising results would be yielded by investigation of the blood-serum before labour. This was now being done. One of the two fatal cases of puerperal sepsis was a woman who had been in labour three days to whom forceps had been applied three times without success. Vagina, perineum, and bladder had been badly torn, and on admission there were hæmolytic streptococci in the blood.

*Abortions and Hæmorrhages.*—Forty-nine abortions had been treated; experience had proved the text-book classification of causation to be unsatisfactory. In the speaker's opinion syphilis did not account for more than 2 per cent. of cases where there was no displacement of the uterus, but traumatic conditions—e.g., coitus—and bad hygienic conditions were prominent causes. As large a number as 16 cases of placenta prævia were treated during the year, three in primiparæ. All the mothers were saved, but the fœtal mortality was high. The best treatment was Braxton Hicks's version; Cæsarean section should be limited to cases where the child was alive or near full term, the placenta central, and the mother elderly, primiparous, uninfected, and anxious for a living child. There had been 27 cases of external accidental hæmorrhage, all of which had had albumin in catheter specimens of urine, and most of them had had pus, blood, and a few casts as well. He considered that for concealed accidental hæmorrhage pituitary extract was a better treatment than Cæsarean section. The drug should be given in doses of ½ c.cm. every half hour up to 3 c.cm. The shock and collapse should be combated at the same time.

*Eclampsia* had reached the high total of 11 cases, four of them in multiparæ. The mothers had been saved, but five children had been still-born. The treatment in all cases had been stomach and bowel lavage, followed by 4 oz. of sulphate of magnesium through the stomach-tube, the withdrawal of 12 oz. of blood from the median basilic vein, and the administration of two pints of saline under the breasts. A ½ gr. of morphine was given immediately on admission and further doses according to the number of fits. It was noted that the violence of the fits and their incidence decreased very markedly with the onset of perspiration, and in no case had any serious manifestation appeared after sweating had begun. There had been nine cases of threatened eclampsia, 14 cases of nephritis, and two of hyperemesis gravidarum.

*Induction of Labour.*—Labour was induced in nine cases. In seven of them the procedure started with 1 oz. of castor oil, followed 13 hours later by 10 gr. of quinine hydrochloride, a high soap-and-water enema in an hour's time, and two more doses of quinine one hour and four hours later respectively. Thereafter six doses of pituitary extract were given half hourly in ½ c.cm. doses, the first being administered six hours after the last dose of quinine. The results were all satisfactory and the large doses of pituitary extract had had no bad effects on the child. There were four cases of uterine inertia and forceps were applied 57 times, with a maternal mortality of one. There were eight still-born children among the forceps cases, four macerated fœtuses, and four children who died after delivery.

### *Discussion.*

The Chairman congratulated the Master on a report which stated what was wrong in the abnormal cases, what treatment was adopted, and what the results were both as regarded the mother and the child. In all these respects this report gave full information. Regarding mortality, he noticed that there were eight deaths, but one of these patients was not pregnant at all, and he thought that patients who were not pregnant should not be included in the mortality list. He would suggest a statement that so many patients were delivered during the year, and out of these there were so many deaths; instead of as was done, saying that so many patients were treated and there were so many deaths. Some of the cases had come into the hospital apparently in an utterly hopeless condition, and he did not think that anything could possibly have been done to save them. He thought that the morbidity was very small and was most creditable to the hospital. There were three cases in which before admission terrible injury had been inflicted by the use of forceps; this pointed to the importance of knowing when forceps should not be used. In two of the cases forceps had been attempted three times before the patient had been admitted to hospital. In another case treated outside the hospital the patient had been left 20 hours in the second stage. This pointed to the necessity for good midwifery teaching. Referring to Cæsarean section in the treatment of hæmorrage he was glad to notice that this operation had been done twice for placenta prævia. He agreed with the rules that the Master had laid down for this operation, but he felt that as time went on Cæsarean section would be done more often for placenta prævia than it had been in the past. The general tendency in obstetrics was to apply this operation more generally for placenta prævia. As to accidental hæmorrhage, statistics were difficult to compile, since it was hard to know when accidental hæmorrhage actually began and when ordinary bleeding stopped. He felt that it was still an open question as to whether Cæsarean section was advisable in cases of accidental hæmorrhage. He was interested to see that the Master now bled and gave morphia in cases of eclampsia, and thought that the fact that morphia had been given in 11 cases among which there had been no death was a good start. He suggested the use of the word "eclampsism" for cases in which there were no convulsions, instead of "threatened eclampsia," and said that he thought accidental hæmorrhage in the worst cases was the same disease as eclampsia. In curettage after abortions, he asked if the Master used a blunt or a sharp curette.

Dr. Gibbon FitzGibbon, referring to the bacteriological examination of cases of sepsis, said that he was interested to note that the two cases who died of acute sepsis both showed hæmolytic streptococci, and that they were both infected during labour; his experience was that cases of acute sepsis were nearly always streptococcal. He did not think that much was gained by examining the blood in these cases. He also had tried injections of N.A.B. in cases of acute sepsis, but thought it had no influence. The Master stated in the report that he thought toxæmia in pregnancy very seldom occurred before the sixth month; he (Dr. FitzGibbon) agreed that it did not often occur before the twenty-eighth week, except in cases where there was a pre-existing nephritis. Referring to the case of post-partum hæmorrhage with a piece of placenta retained, he said that in cases where the placenta could be got away by a moderate application of Credé's method it was all right to do so, but if this was not possible he, personally, preferred to do a clean manual removal of the placenta. He quite agreed with the Master's view regarding the conservative treatment of cases of accidental hæmorrhage. He noticed that the Master looked upon the occurrence of sweating as a good prognostic sign, and said that formerly patients were put in hot packs to try and promote sweating. He thought that when sweating occurred it was evidence of recovery rather than the cause of it. Regarding the treatment of placenta prævia, he said that he thought it was important to know whether the patient had been 36 or 38 weeks pregnant before deciding what treatment to adopt for this condition. Referring to hyperemesis, he said that he thought the important thing was to find out what the cause of the hyperemesis was. In the case described by the Master he did not think pregnancy was the cause; he thought it was probably a toxic case, as the patient suffered from diseased kidneys. The Master's treatment of cases of uterine inertia was quite different from that practised by the speaker at the Rotunda, and whereas all Dr. Cassidy's cases ended in dead babies, he (the speaker) had got 75 per cent. live babies out of the cases sent in to the Rotunda Hospital, using sedative treatment. In cases of hydatidiform mole, Dr. FitzGibbon induced uterine action by sea-tangle tents, and then emptied the uterus; he did not do hysterotomy. He thought that there were far more toxæmic patients who were chronic nephritis cases than was generally realised, and a great many of these did not clear up with treatment. He was surprised at the finding of albumin and blood in the urine in so large a percentage of all cases. He was interested to note the number of cases that had shown tubercle bacilli in the urine, as on four occasions he had found these in cases of persistent pyelitis. Referring to the post-mortem examination of babies, he said that he carried this out to a small extent, but he did not mention it in the Rotunda Hospital report, owing to the negative findings. In several cases it was found that the baby had died from some congenital condition, which would not have been suspected except for the post-mortem.

Dr. **Bethel Solomons** suggested that the cause of morbidity and mortality among women who had not been examined vaginally was due in many instances to the faulty conduction of the third stage of labour with retention of membranes, although this retention could occur without pyrexia. He questioned the advisability of giving pituitary extract in placenta prævia. The average student was bewildered by the various views held about accidental hæmorrhage. He hoped that examiners would accept standard views and treatment; there were very few cases of true concealed hæmorrhage. The results in eclampsia from the Rotunda treatment modified by the inclusion of venesection were most satisfactory. Although blood pressure was estimated, 12 oz. of blood were withdrawn as a routine, irrespective of the estimation He thought that some of the cases of uterine inertia would have been better if left alone; he found the Walcher position of great benefit when pains did commence in these troublesome cases, and uterine sedatives were better than stimulants. The pathological report was of great value, and biochemical tests in pregnancy and other laboratory methods should be taught, but it was important to remember in these days that practical clinical instruction was of greater service to the student and the post-graduate who might later be working in places where he could not call in the assistance of the pathologist and the biochemist. With regard to the cause of abortions, many of these were hormonic in origin. In the gynæcological report there were 90 curettage and 25 Alexander Adams operations. The indications for curettage were few, and the disadvantage of not opening the abdomen to correct the position of the uterus was great. Wertheim's operation had been done for "suspected" malignant disease on two occasions. Did the microscope reveal malignancy?

Dr. **A. H. Davidson** drew attention to the fact that in this report the Master had stated that syphilis did not account for more than 2 per cent. of abortions, whereas in the report of the previous year syphilis had accounted for a much larger percentage of abortions. He also drew attention to the danger of giving large doses of pituitary extract in cases of accidental hæmorrhage when the vagina had been plugged; he had seen two cases while at the Rotunda in which rupture of the uterus had followed this treatment. The Master said in the report that in cases of uterine inertia the os was dilated and forceps applied, in the hope of saving the child He (Dr. Davidson) thought that in cases of uterine inertia, where the conditions for the use of forceps were not fulfilled, it was hopeless to attempt to save the child, as the child was always killed by bringing it through an undilated passage, and harm was done to the mother at the same time. He was very interested in the report of the treatment of cases of parametritis by radiant heat, and asked what the results had been, as it seemed to him a good method.

Dr. **D. J. Cannon**, referring to uterine inertia, said that sometimes good results were obtained by the giving of pituitary extract and sometimes not. He asked whether it would not be possible to discriminate between the cases which needed this drug and those which only needed ordinary treatment. In cases of concealed accidental hæmorrhage shock was the essential cause of the hæmorrhage, whatever the cause of the shock might be, and in the case of accidental hæmorrhage which died he wondered whether, if morphia had been given instead of pituitary, the result would have been better. Referring to morbidity, he asked if a vaginal examination was made when looking for the cord, or if in the Coombe Hospital they just waited till the cord appeared. If this was done he thought there was a danger of sepsis, and that then, strictly speaking, the cases would not be cases of spontaneous labour.

### *Reply.*

The **Master** of the Coombe Hospital, in replying, said that Cæsarean section was done a good deal for placenta prævia, because this condition occurred so often in multiparæ or in women who were not more than 32 weeks pregnant. Cæsarean section should never be undertaken with the object of saving the child's life unless the child was 36 weeks old, as up to that time the child was very small. In cases of eclampsia he thought that bleeding should be done independently of the condition of the pulse; the giving of morphia in these cases might have a great deal to do with the question of fœtal mortality. In cases of curettage after abortions he used a blunt curette. In cases of sepsis he thought the examination of the blood was of value if the blood was taken when the temperature was high; after a rigor the chances of demonstrating streptococci were fairly good. As yet there was no really definite form of treatment for cases of sepsis, but in some cases he had found that the injection of N.A B. intravenously had produced most dramatic results. In cases of abortion it was practically impossible to demonstrate any change in metabolism before the twenty-fourth week. He had never seen any danger occur in any case from the use of pituitary extract in cases of accidental hæmorrhage Referring to the routine examination of urine, he said that by this means they had found that the presence of pus in the urine in pregnant women was very frequent, and albumin was also found in a very large percentage of cases. Pituitary extract was only given in cases of placenta prævia, when there was a definite hope that by small doses it would be possible to stimulate uterine contractions. In some cases it was valuable, but the chances of rupture of the uterus in cases where it had been used were much greater than in cases where it had not been used. No septic cases had been sent out of the hospital. One patient, who had a perfectly normal puerperium, left hospital against the wishes of the staff on the ninth day and died from acute sepsis at home on the fourteenth day. Most of the curettages were done as a result of abortions, and he thought that it was a good thing to do this operation after an abortion. Before Alexander Adams's operation was done the tubes were always tested. Both the suspected cases of carcinoma had turned out later to be carcinoma. Every case, of course, must be judged on its merits, and he was of opinion that pituitary extract was a most useful drug to give if given with common sense. The results in cases of parametritis from radiant heat treatment had been very satisfactory.

---

**London Dermatological Society.**—The annual oration of this society was delivered on June 16th at St. John's Hospital, Leicester-square, by Sir Humphry Rolleston, on the Relations of Dermatology and General Medicine. Dr. W. Griffith, the President, was in the chair. At the conclusion of the meeting a vote of thanks to the orator was proposed by Dr. Knowsley Sibley, and seconded by Dr. J. M. H. MacLeod. The annual dinner was held at the Trocadero Restaurant after the meeting. The following were among the official guests of the society: Sir Humphry Rolleston, Dr. J. H. Stowers, Dr. J. H. Sequeira, Dr. H. Haldin Davis, Dr. H. W. Barber, and Dr. H. G. Adamson.

# ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

AT a meeting of this Society on June 17th, at the rooms of the Medical Society of London, the chair was occupied by Dr. ANDREW BALFOUR, the President.

### *Presentation of the Manson Medal.*

Before the regular business of the meeting the Manson medal for researches in tropical medicine was presented by the President to Prof. Ettore Marchiafava, of Rome, an honorary Fellow. The felicitations of Dr. Balfour were supplemented by those of the Italian Ambassador and Baron San Severino.

### *Malaria in England.*

Lieut.-Colonel P. JAMES, I.M.S. (Ministry of Health), then read a paper, which was liberally supported by microscopical preparations, on Epidemiological Results of a Laboratory Study of Malaria in England. The official arrangement in this country, he said, by which general paralysis and other mental diseases could be treated by a course of malarial attacks induced by the bites of infected mosquitoes, gave an opportunity of studying, in the laboratory, certain factors of importance in the epidemiology of malaria. The practical object of the work was to provide a sufficiency of mosquitoes to induce a pure infection of benign tertian malaria in patients to be treated. During the period referred to 221 patients received their bites, and of these 169 developed benign tertian malaria within the usual incubation period.

Observations were made, during the routine work, on factors concerned in the transmission of malaria from man to mosquitoes and from mosquitoes to man. It was found to be difficult to bring even a few members of a large brood of mosquitoes to such a condition that they would be successful transmitters of malaria. Among the reasons of this were the following. It was difficult to find a malaria patient who was infective to those insects. In the feeding experiments about three days must elapse before the gametocytes became infective to anopheles, so that a patient in a first attack of malaria did not become infective until quite the tenth day of his illness. But in relapses, gametocytes were present much earlier. One of the most important factors in the infection of anopheles was the number of feeds on infective blood needed before a batch of them became infective. With regard to the influence of temperature, humidity, and season, the experience was that the best results in infecting *Anopheles maculipennis* with *P. vivax* were obtained at temperatures between 22° and 24° C., and in a saturated atmosphere. Another point was that mosquitoes carrying nearly ripe eggs did not suck nearly so much blood as did others, because the swollen ovaries filled the abdomen and pressed so much against the midgut that its cavity was almost closed. When the mosquito fed on certain fruits and foods other than fresh blood the reaction in the stomach was unfavourable to oöcyst development. Fresh human blood seemed to be the only suitable food for the purpose. Some of the mosquitoes fed greedily, some only slightly, therefore they were fed repeatedly on the infecting patient. The mortality of the *maculipennis* above 22° C. was high. It was clear that many special conditions had to be fulfilled in Nature before malaria could be transmitted from man to mosquito, and this would explain why malaria was essentially a "household disease." Some of the mosquitoes in the successful batches lived and continued to be infective for from 29 to 92 days after sporozoites were present in their glands. It seemed that *P. vivax* could be carried through even a severe winter in hibernating mosquitoes, and an infected mosquito nearly always carried zygotes at several stages of development.

The observations which were made by Colonel James and his assistant, Mr. Shute, showed that c [illegible] anopheles mosquitoes became transmitters of malaria. The reason that in many places all the inhabitants had the disease was that when once a mosquito had become infected it continued so for a long time, and could infect many people. It seemed to be beyond doubt that in Nature the only mosquitoes which became transmitters of malaria were those which passed their lives in sheltered and peculiar conditions, like those in the laboratory. Much effort was being wasted when directed against the breeding places of mosquitoes as a whole, and especially in anti-larval measures in the fields and marshes, leaving the mosquito to work its fell will in the houses of the people. The life habits of the particular infective kind of mosquito must be studied, as they differed widely from those of the specific group to which they entomologically belonged. The human dwelling seemed to be the "laboratory" where malaria infection had its origin and was cultivated.

In conclusion, Colonel James said the point had been reached at which the services of the physiologist and the biochemist were needed to say whether there were chemical differences in the blood of the three classes of patients he had called attention to whose blood differed so widely in the degree of hospitality it offered to malaria. And it would be excellent if a test could be devised which would enable patients to be classified in this regard.

### *Discussion.*

Sir PERCY BASSETT-SMITH drew attention to a lesson taught by the research—namely, that those who were engaged in out-of-door occupations did not readily develop malaria, which seemed to show that the amount of exercise they had increased their phagocytosis.

Colonel CLAYTON LANE said that in his view the *maculipennis* was an insect which was sick with malaria, and that was why only a small percentage of the females under observation survived. Hence a heavily malaria-infected mosquito was a source of less danger to the community than a lightly infected one, and it might be that this was a factor in the restriction of the spread of malaria. The most important problem in malaria was that of house infection.

Dr. H. M. HANSCHELL confirmed the remarks of the last speaker, and said that there should be a stricter use of the mosquito net; it was not supplied to the coolie with the same energy as was quinine. He also advocated the use of mosquito traps, and described those which he used in Barbados.

Mr. AGARTH suggested, as an entomologist, that the differences found in persons in their reactions to the bites of infected mosquitoes might be a matter of the relative acidity or alkalinity of the blood, and that the point might be settled by biochemists. Some rat-catchers seemed never to be bitten by rats, or if they were they did not seem to develop ill-effects.

Lieut.-Colonel C. A. GILL, I.M.S., said that the results obtained by Colonel James made it necessary to revise the accepted views on the subject. Two difficulties were the impossibility of measuring the susceptibility of the host and the dose of infection of the sporozoites being given to the patient. He did not agree with Colonel Lane that the house mosquito was sick with malaria.

Dr. H. S. STANNUS remarked on the fact that heavy drinkers in the tropics were very insusceptible to malaria, possibly because mosquitoes did not relish alcohol.

Sir ALMROTH WRIGHT suggested that in his next investigation Colonel James should have the assistance of half a dozen laboratory workers, as the work promised some valuable conclusions on the question of immunity.

Dr. W. RUDOLPH said that by inoculating patients suffering from general paralysis of the insane one could know what the dosage was if infected blood was used, and that was what had been done at the London County Council mental hospital at Claybury. Some of the cases there could not be made to develop malaria, and he suggested that the difference might be related to the glucose content of the blood By adding glucose to the blood one produced sporulation, which did not occur without the glucose At Claybury this treatment of general paralysis had been carried on since August, 1923, and 240 cases had been worked out. Among untreated cases, 77 per cent. died within a year of a remission occurring, whereas 68 per cent. of 63 cases at Claybury with an 18 months history at least had been discharged The outlook for cases with a longer history was less satisfactory, and this supported Colonel James's contention All the patients he was referring to were fully certified

Dr P Manson-Bahr expressed the view that many of the so-called clinical results were not produced by drugs, but were the results of host immunity—in other words, the environment of the patient—and much depended on the patient's state of health Quinine and some other drugs probably did what Nature accomplished in other ways. He saw great possibilities from Colonel James's inquiry

The President, in summing up the discussion, related some of his own experiences. He agreed with what Colonel James said about house infection in this country, but he was sure the remarks did not apply to the tropics.

Colonel James, in his brief reply, accepted Sir Almroth Wright's offer of skilled laboratory assistance in the further stages of this work He again emphasised the great importance of house infection

## Industrial Psychology in Great Britain

By Charles S Myers, M D, D Sc., F R S, Director of the National Institute of Industrial Psychology London: Jonathan Cape 1926 Pp 164, 7s 6d

Modern industry is an unforeseen product of human activities, and a basic biological cause of industrial unrest is the difficult adjustment demanded of human nature in face of conditions that give little opportunity for the satisfaction of instinctive desires and tendencies. The desire to make or produce things, for example, is a driving force that found easy expression until modern subdivision of labour deprived the individual worker of the sense of achievement If the only stimulus to work is the need to earn one's daily bread, then interest in that work loses any intrinsic worth, and minor discomforts and difficulties that would be overcome by adequate interest now form serious obstacles to efficiency Since the worker himself is unaware of the mental processes concerned, there arises a vague discontent attaching itself to any chance object or showing itself by inefficient work or irrational behaviour

Faced by these conditions, industrial psychology endeavours to replace the methods of trial and error by a systematic study of the reactions of wage-earners in response to different surroundings. Dr Myers describes how this aim is being reached by the Industrial Fatigue Research Board and the National Institute of Industrial Psychology Begun under the necessity of the war, the work is becoming more and more valued, though one of its results is the formulation of hitherto unsuspected problems. Occupation neuroses, like telegraphist's cramp and miner's nystagmus, have been ascribed to simple causes such as posture or illumination, but Dr Myers finds that evidence is accumulating that the mental factors of worry and anxiety play an important, perhaps the essential, rôle in their causation. Psychoneurotic conditions generally are not to be regarded as the prerogative of intellectual workers or the leisured classes.

A misconception of the aim of industrial psychology has to be guarded against Increase in the comfort and happiness of the worker results in increased output, which is gratifying to the employer and serves as a measure of the benefits obtained, but is not to be regarded as the chief end in view "Speeding up" is not the aim of industrial psychology, and workers whose output has been incidentally raised have often expressed gratitude for increased comfort and lessened fatigue. Dr Myers himself would admit that the work here described under such headings as organisation, fatigue, movement study, and vocational guidance only touches the fringe of many problems that closely concern our industrial efficiency and national prosperity His book is an encouraging record of the results of psychology applied in a sphere where the need for its application is very great.

## Gastric Function in Health and Disease.

By John Ryle, M D Lond, F R C.P, Assistant Physician and Lecturer on Medical Pathology, Guy's Hospital. London Humphrey Milford 1926 Pp 152 8s 6d.

Our readers are, many of them, familiar with Dr Ryle's Goulstonian lectures, which were published in The Lancet (1925, i, 583, 642, 697, and 754) We welcome their appearance in book form because they contain not only a survey of all the more important recent researches in connexion with gastric disease, but include many interesting and scholarly expressions of opinion by the author himself Dr Ryle has been at pains to confine himself chiefly to recent investigations His chapter on the secretory functions of the stomach in health might have been improved by fuller reference to the known facts concerning its mechanism, sparse though such facts be The influence of certain drugs in initiating secretion is, for example, evidence requiring consideration The well selected references included add to the value of the book to all those engaged in the investigation of gastric diseases.

## Chronic Disease: A Working Hypothesis.

By E Bach, M.B, B S., D P H, and C E Wheeler, M D, B S., B.Sc. London: H K. Lewis and Co 1925 Pp 158 7s. 6d

The authors believe that chronic intoxication with non lactose-fermenting organisms of intestinal origin is the chief underlying factor in chronic diseases of diverse types They have treated upwards of 500 of such cases by a diet consisting largely of uncooked vegetable food, together with vaccines, and believe that their results point to such therapeutic measures being of high value We find nothing that is logically convincing in their work, and we trust that the authors will recognise that in saying this we in no way imply that their hypothesis is inaccurate, but that until some definite physical or laboratory indications of chronic intestinal intoxication can be demonstrated beyond doubt, we remain sceptical.

In putting their views to practical test the authors are nevertheless pursuing a valuable work, and we shall welcome further observations from them They write with restraint and enthusiasm combined, and there is perpetual need for clinical inquiries such as they are making

## Collected Papers

Vol IV. By Sigm. Freud, M D, LL.D Authorised translation by Joan Riviere. London: Hogarth Press 1925 Pp 508 21s

The contents of this, the final volume of Freud's collected papers, fall into two parts. The first is devoted to what Freud calls meta psychology, a term by which he means the consideration of a given mental process in accordance with his conceptions of "depth psychology," and with the dynamic factors concerned and the ends served by the process. This triple aspect of mental processes certainly goes beyond the purview of non analytic psychology, but then seems no sound reason for thus accentuating a difference which, in the interests of scientific principles, should not exist. Freud himself argues that the postulate of an unconscious rests upon evidence as strong as that which justifies us in speaking of a consciousness, though to imagine mental processes as having topographical relationships one to another certainly appears to give a false value to what are only conceptions; but there is pragmatic justification for the hypothesis as a convenient means of generalisation. The chapters on instinct, repression, and the unconscious form a connected exposition of the fundamental concepts of psycho-analysis which, though lacking in actual evidence such as the earlier volumes furnish, should be studied by those who find difficulty in giving a scientific status to those concepts. We note the free use of the word "cathexis," but have failed to find a definition of it; it seems to indicate the emotional charge attached to an idea. In the opening paragraph on the topography and dynamics of repression (page 112) we read that repression "must be a matter of withdrawal of cathexis" and then that "it must be something else which has been withdrawn"; possibly there is here a departure from the high standard of translation shown generally in the book, for the passage is difficult to follow.

The second part is a collection of essays, some written as long ago as 1908, treating of non-medical applications of psycho-analysis. The antithetical sense of primal words, a special type of choice of love-object by men, the Moses of Michael Angelo, the "uncanny," a neurosis of demoniacal possession, are some of the subjects handled; in every case, whether the reader is in agreement or not with Freud, he will grant that the handling is original and that interest is aroused to an unexpected degree. "Thoughts for the Times on War and Death," dated 1915, offering an objective view of war-time reactions at that time rare in any belligerent country, could not have lessened the intellectual isolation of the writer which already existed. The chapter on dreams and telepathy, in which a definite pronouncement might have been expected, is entirely non-committal as regards the reality of telepathy in the occult sense. These later chapters may stand as a reward for readers who have, not without effort, worked through the more technical parts of the preceding volumes. This volume contains an index to all four, as well as a bibliography of Freud's writings on psycho-analysis.

### DIAGNOSTIC AND THERAPEUTIC ERRORS.

*Diagnostische und Therapeutische Irrtümer und deren Verhütung.* Edited by Prof. J. Schwalbe. Part VII., Injuries and Surgical Diseases of the Mouth, Throat, and Neck. By Prof. Paul Clairmont. Leipzig: G. Thieme. 1926. Pp. 188. M.8.10.

When reviewing Part XIV. of this series, which appeared in 1922, we remarked that mistakes cannot be discussed without entering pretty thoroughly into the whole subject of diagnosis and treatment of the diseases in question, but that such a work affords an interesting opportunity of approaching these subjects from an angle somewhat different from that offered by the systematic text-books. These remarks apply equally to the present volume, which deals with a great variety of subjects ranging from cleft-palate and diseases of the tongue, to diseases of the larynx and œsophagus. They are discussed from the standpoint of the general surgeon rather than of the laryngologist; indeed, diseases of the larynx and trachea occupy but five pages of text; their consideration is far too abbreviated to be of value and might well have been omitted. The most interesting part of the book consists in the description of diseases and tumours of the neck; wry-neck, cervical ribs, tumours of the salivary glands and of the thyroid gland are discussed, and many rare cases are illustrated. The pictures are excellent, and skiagrams of uncommon cases abound. The volume will provide a store of interesting rea[illegible] surgeons and laryngologists.

### NEUROLOGY.

*Les Tumeurs du Cerveau.* By Prof. Viggo Christiansen, Chief Physician to the Royal Hospital of Denmark. Second edition. Paris: Masson et Cie. 1925. Pp. 399. Fr.45.

We reviewed this book on its first appearance in 1922, commenting on its form as a series of clinical lessons or lectures, and pointing out that it could scarcely be regarded as a complete monograph on its subject, since several varieties of intracranial neoplasm were not mentioned. This second edition is amplified and largely rewritten, and contains material, especially in regard to chiasmatic tumours, which did not appear formerly. At the same time, it lacks that comprehensiveness of treatment which the subject demands. Its clinical value resides mainly in its diagnostic analyses and its graphic and informative accounts of tumour cases. Prof. Christiansen has had reason to modify to some extent his opinions on the results of surgical treatment, more particularly in respect of decompressive operations; he now regards such surgical interference more hopefully than before.

*Syndromes Neuro-Anémiques.* By Dr. Pierre Mathieu, Ancien Interne des Hôpitaux de Paris. Paris: Gaston Doin. 1925. With 20 illustrations and one plate. Pp. 172. Fr.20.

The problem of the pathogenesis of what is usually called in England subacute combined degeneration of the spinal cord still awaits solution. This disease is common, and always serious; hitherto, as usual, too much attention has been devoted to its morbid pathology and too little to experimentation. The condition, further, has been regarded as something sui generis, whereas, as Dr. Mathieu urges with every reason, it is rather a syndrome than a morbid entity. Two of his cases were, as a fact, associated with unsuspected malignant growths of the intestine. In his monograph all that is known of the subject is set forth clearly and concisely, with good bibliographical references, and his own clinico-pathological examples are fully detailed. He is not satisfied either with a vascular or a funicular theory of the spread of the disease, and suggests there is a relationship between certain toxins and certain anatomo-physiological mechanisms of the cord, relying for analogy on known connexions between certain toxins and certain peripheral nerve-mechanisms. The book is a useful contribution to a difficult topic, which has as yet scarcely passed the stage of mere description.

*Brain and Spinal Cord.* A Manual for the Study of the Morphology and Fibre-tracts of the Central Nervous System. By Emil Villiger, Professor in the University of Basel. Edited by William H. F. Addison, B.A., M.D., Professor of Normal Histology and Embryology in the University of Pennsylvania. Third revised American edition. London: J. B. Lippincott Co. 1925. With 262 illustrations, many in colour. Pp. 335. 25s.

Prof. Villiger's text-book of nervous anatomy is well known both in its German and English editions, and has stood the test of time with success, for it first appeared more than 20 years ago and has had more than one review in our columns. Its conspicuous feature is its reliance as much on illustrative as on textual exposition. In the latest edition many changes have been made; there is a new section on the sympathetic nervous system, while additions to knowledge have been incorporated chiefly in regard to the cerebellum and brain stem. In view of the importance of the basal ganglia from the standpoint of nervous disease we do not think sufficient elaboration of their structure and connexions is given by Prof. Villiger. To describe only three nuclei in the optic thalamus is not enough; moreover, the relations of the corpus striatum with various small ganglionic collections in the midbrain and elsewhere should be set forth in greater detail. It is misleading, in our opinion, to describe corticofugal fibres passing by the corona radiata to caudate and lenticular nucleus; the substantia nigra is dismissed too briefly, and connexions of the corpus striatum with the nucleus of Darkschewitsch, inter alia, are ignored. As a general survey of neuro-anatomy, however, the book fulfils its avowed purpose.

*"Kinésie Paradoxale" des Parkinsoniens.* Contribution à l'Étude du Mecanisme de la Motilité Volontaire. By Dr. J. JARKOWSKI. Paris: Masson et Cie. 1925. Pp. 78. Fr.12.

THIS is an interesting little monograph worthy of attention from the neurologist. Briefly, it sets out to explain the curious variability in Parkinsonian rigidity. As has long been recognised, patients who suffer from paralysis agitans are often able at one time to perform an act which at another seems to be impeded; again, Parkinsonians can sometimes run when they are almost incapable of walking. The author endeavours to show that they suffer from a reduction of the "impulse" to move, which itself is a consequence of impairment of "affectivo-motor" reactions; these constitute the "proto-energy" of the individual, according to the author's expression. Should what remains of this "proto-energy" be sufficient on occasion to assert itself, the Parkinsonian can and will move; if an external stimulus be on occasion adequate, the same result will ensue. Thus the conclusion is reached that the impediment which he encounters is not merely mechanical, a consequence of a rigid voluntary musculature; there is a psychical or psychomotor component of equal or greater significance.

Somewhat similar views have been expressed by other research workers, notably by Kinnier Wilson in his recent Croonian lectures. The slender volume of Dr. Jarkowski can be recommended to all who are interested in the problems of motility.

## JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE. May, 1926.—A method of estimating in a scientific way permanent disability resulting from accidents is put forward by H. H. Kessler. He holds that functional disability, after the clinical condition has become permanent, must be accurately measured, personal opinion being quite unreliable. Mensuration is determined by such instruments as Martin's spring balance, and a description is given for applying the method to estimate loss of function of the component parts of the upper limb, the arm radicle, and the hand radicle. The article is of interest to all who are called upon to appraise compensation claims.—After investigating 331 persons exposed to lead risk, but not cases of acute lead poisoning, M. R. Mayers holds that lead anæmia is a blood disease entity, an anæmia of low secondary grade with stippling of red cells as a prominent feature, associated with other distinctive cellular changes. The ashen pallor depends on neurovascular capillary disturbance rather than on hæmoglobin content. The blood picture is of material assistance in troublesome cases of compensation.—A study of the relation of illumination to rapidity of post office work is described by J. E. Ives and E. Sydenstricker. First, two offices are contrasted, one (A) which worked entirely with artificial light, and the other (B) with good daylight for 40 per cent. of the time; in both artificial light had a high average value of 8·5 foot-candles. In all 2410 employees were examined with the following results (expressed as percentages), which indicate that the poorer illumination at A had an injurious effect on the eyes:—

| — | Both eyes normal. | Both eyes defective. | Inflammatory conditions. | Muscular unbalance. | Asthenopia. |
|---|---|---|---|---|---|
| A | 10·3 | 42·5 | 20·9 | 33·4 | 16·5 |
| B | 19·8 | 32·6 | 11·9 | 22·4 | 6·7 |

The defects increased with age and in order of greatest eye work, thus:—

| — | Under age 45. | | Over age 45. | |
|---|---|---|---|---|
| | Labourers. | Letter separators. | Labourers. | Letter separators. |
| Normality .. | 81·4 | 65·5 | 38·5 | 20·0 |
| Inflammatory conditions | 12·7 | 20·9 | 13·5 | 37·2 |

Various tests were carried out which showed that the rate of letter-sorting increased rapidly as light was increased from low illumination, but that as an illumination of 8 foot-candles is approached, the rate of increase rapidly diminishes until it attains a maximum beyond which increase of light has no effect. This study has opened up new ground and further problems which are now under investigation.

# Reports and Analytical Records.

## BEEFEATER LONDON DRY GIN.

(JAMES BURROUGH, LTD., CALE DISTILLERY, HUTTON-ROAD, LONDON, S.E. 11.)

GIN is a potable spirit flavoured with the volatile products of juniper berries and sometimes with those of other aromatic herbs. The spirit employed is usually from the patent still and is made from cereals. Gin is rarely adulterated and is probably one of the most harmless forms in which alcohol can be consumed. When "Beefeater" gin was analysed the following results were obtained:—

| | |
|---|---|
| Alcohol per cent. by volume .. | 42·7 per cent. |
| Alcohol per cent. as proof spirit .. | 74·75 ,, |
| Equivalent to .. .. .. | 25·25 under proof |
| Volatile acidity as acetic acid .. | 0·002 per cent. |
| Extractives .. .. .. .. | 0·016 ,, |
| Ash .. .. .. .. .. | 0·009 ,, |

| Secondary constituents | Mg. per 100 c.cm. of absolute alcohol |
|---|---|
| Volatile acidity as acetic acid .. .. | 4·7 |
| Fixed acidity .. .. .. .. | Nil |
| Furfural .. .. .. .. .. | Nil |
| Aldehydes .. .. .. .. .. | 2·0 |
| Esters as ethyl acetate .. .. .. | 12·1 |

These figures are normal for a good gin. "Beefeater" gin may be regarded as a sound unsweetened spirit of high quality.

## CARYPTON AND ANGOSTURA BITTERS.

(PREPARED BY DR. J. G. B. SIEGERT AND SONS, PORT OF SPAIN. SOLE CONSIGNEES: HENDERSON AND CO. (LONDON, LTD.), FINSBURY COURT, FINSBURY PAVEMENT, LONDON, E.C. 2.)

This preparation is mixed with crushed ice and consumed as a cocktail. When analysed the following results were obtained:—

| | |
|---|---|
| Alcohol .. .. .. .. | 21·8 per cent. by volume equivalent to 62 per cent. underproof |
| Total solids .. .. .. .. | 12·5 per cent. |
| Consisting of cane sugar .. | 10·8 ,, |
| Extractives .. .. .. | 1·7 ,, |
| Ash .. .. .. .. .. | 0·06 ,, |
| Volatile acidity as acetic acid .. | 0·05 ,, |
| Fixed acidity as citric acid .. | 0·30 ,, |

The alcohol used is derived from rum and the extractives other than sugar from various herbs indigenous to the West Indies. Quinine was tested for with negative results. "Carypton" has an agreeable odour and flavour. The slight bitterness is "clean" and does not remain on or clog the palate in the slightest degree.

Angostura bitters, which may also be regarded by virtue of the high alcohol content as a liqueur, were first introduced in 1833 by J. H. G. Siegert, of Venezuela, and are said to have been brought to Europe in 1830 by von Humboldt, the explorer. The bitters are commonly supposed to be compounded of angostura bark (cusparia), chamomile, cardamom, cinnamon, orange peel, raisins, alcohol, and water, of which the first mentioned contains small amounts of alkaloids. On analysis the following results were obtained :—

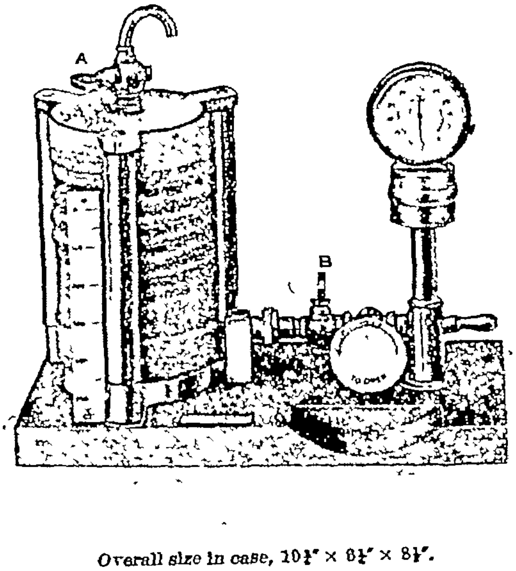
| | |
|---|---|
| Alcohol by volume .. .. .. | 48 per cent. |
| Equivalent to .. .. .. | 15·0 under proof. |
| Total solids .. .. .. | 0·53 per cent. |
| Water .. .. .. .. | 45·30 " |
| Ash .. .. .. .. .. | 0·10 " |
| Volatile acidity as acetic acid .. | 0·007 " |
| Fixed acidity as citric acid .. | 0·06 " |
| The total solids consist of— | |
| Cane sugar .. .. .. | 5·0 " |
| Extractives not sugar (resins, alkaloids, &c.) .. .. | 1·53 " |

The preservatives, salicylic and benzoic acids, were absent. Quinine was tested for with negative results.

# New Inventions.

## A PORTABLE PNEUMOTHORAX APPARATUS.

THE pneumothorax apparatus here illustrated has been designed to meet three conditions: (1) absolute portability, there being no fluids in any part; (2) simplicity of manipulation, the instrument can be controlled with one hand all through the operation; (3) the air or gas is under constant pressure at all times, and can be introduced into the patient's chest at any desired pressure up to 25 cm. of water. The apparatus consists of a collapsible bellows made of double-lined rubber canvas, supported by three guides, and arranged so as to fall steadily under the weight of a metal cap attached to the tubes which slide over the three guides. A graduated scale shows the amount of air at any moment in the bellows, which when full hold approximately 500 c.cm. A tap is placed on the top of the bellows for the purpose of filling them with air, or any gas desirable, whilst at the base is the outlet which leads the air or gas through a second tap and a reducing valve. A manometer is fixed at this point which is in direct connexion with the pneumothorax needle. The insertion of a second manometer between the bellows and fine adjustment valve is not really required, as the air in the reservoir is under constant pressure. A simple air filter is placed between the manometer and the needle. In use the tap B is closed and the tap A opened. The bellows are raised by the hooked tube until the stop is reached. The tap A is then closed. This can be easily performed with one hand, and can be repeated as many times as desired during the operation. The reducing valve between the tap B and the manometer is then closed, and the manometer adjusted to zero. The needle is then inserted into the pleural cavity, and as soon as this is reached a good oscillation of the needle on the manometer dial will be noticed. The tap B is then opened and the reducing valve is *very slowly* unscrewed, until an increase in the mean of the oscillation of the needle is noticed. This indicates that the air or gas is flowing from the bellows into the pleural cavity. The amount of air desired is allowed to pass into the patient's chest, and then tap B is closed, and a reading of the intrapleural pressure obtained. If it is insufficient the tap B is opened again, and the rate of the flow of gas or air adjusted by the reducing valve. If more air is required than the capacity of the bellows, the tap B and the reducing valve are closed, tap A opened, and the reservoir filled as before. A good knowledge of the flow of air can be readily obtained by noticing the rising mean pressure registered by the manometer. This latter part of the apparatus has been found very reliable, but for safety it can be easily tested against a water manometer every month. The instrument possesses a distinct advantage over former water-syphon types, in that the pressure of the air or gas emitted from the reservoir does not decrease as the operation proceeds and can be completely controlled by the reducing valve.



Overall size in case, 10½″ × 8½″ × 8½″.

The complete instrument is manufactured by Messrs. Philip Harris and Co., Ltd., Birmingham.

FREDERICK HEAF, M.D. Camb.

## A NEW TEST FOR THE LIGHT SENSE.

LIGHT minimum tests are valuable in such diseases as retinitis pigmentosa, luetic retinitis, hereditary night blindness, and generally speaking in diseases of the retina or choroid as distinguished from those in which the *conducting fibres of the optic nerve* are impaired. Lowered ability to recognise the proper threshold value of light is due to damage to the perceptive rods of the retina, whereas when the patient's statements in the light difference test are appreciably at variance with the law of Fechner, then the conducting power of the optic nerve is impaired. In many chronic cases of secondary optic atrophy the values of both the light minimum and the light difference are considerably removed from the normal values in the same patient and at the same time. Eighteen months ago I devised an apparatus for the accurate determination of a patient's sensitiveness to light *increments* superimposed upon the initial source of an illuminated area. The apparatus in its original form was rather cumbersome, but the construction has now been simplified so that only one source of light is necessary, and the use of filters has been dispensed with. The optical system used gives a definite comparison between two areas of light, made apparent to the patient by interposing different stencils of various letters. The special diffusing screen gives *true definition at an angle of 15° either* side of the normal. The percentage increase of intrinsic brightness is indicated by black figures on an illuminated background at the side of the instrument discernible to the operator only. A shutter cuts off the main illumination to enable the light minimum by comparison to be obtained. The instrument, which is made by Mr. Clement Clarke, 16, Wigmore-street, London, W. 1, has been tested against Lummer Brodhan standard photometers.

has aggravated the hardship of existing officers. But real injustices exist. Figures can be brought forward, for example, to show that after the war the alterations in pay for the officers of the R.A.M.C. were not comparable to those made for officers in the line regiments, a repercussion of the old mental confusion between the situation of the gentleman cadet entering his corps to receive his training at the expense of the State and the medical officer joining a Service after five or six years of intensive professional training conducted at private expense. Quite rightly the commencing pay of the latter was fixed at a higher rate than that of the former, but the reason for this was lost sight of when, as an excuse for not improving the salaries of medical officers to the extent that the salaries of the officers of the line were raised, it was put forward that the former were already in receipt of better pay.

We are informed that the recommendations of the Departmental Committee to which effect is now to be given in the expected Orders deal substantially with the whole situation along the lines put forward by Sir WILLIAM LEISHMAN, and advocated by the British Medical Association in their evidence before the Committee. There will be considerable increases of pay to the middle ranks, equalisation of specialist pay, and some redress of the unfair reduction of pensions, made apparently in breach of contracts which were in force between the State and the officers concerned. That the occurrence of such breaches should be viewed with apparent equanimity in high places has formed a critical episode in a long story of effort for redress. We may look forward under the new conditions to fine results. Those who grasp promptly the opportunities now offered will reap the advantage of early promotion in return for meritorious work.

◆

## PROTEIN SHOCK THERAPY.

LONG before the discovery of anaphylaxis and the consequent awakening of interest in the workings of protein shock, WAGNER-JAUREGG in Vienna was injecting proteins into the blood of general paralytics and satisfying himself of a measure of therapeutic success in so doing. Starting from an old clinical observation that an attack of fever might be beneficial in certain types of psychosis, he was seeking the most suitable method of producing it artificially. Finally, abandoning the proteins of commerce and dead bacilli, he hit on the parasite of benign tertian malaria and elaborated the malarial treatment of which so much has been heard. His colleagues in Vienna are still working on this remedy, the mechanism of which is obscure, for in spite of their efforts no evidence has been brought forward to establish the malarial toxin as having any specific effect. The success of protein shock therapy with the group of chronic nervous diseases has encouraged its trial with other intractable maladies. In an article which appears in our present issue, Dr. W. YEOMAN records an application of non-specific protein injection to old-standing cases of arthritis in the Royal Bath Hospital at Harrogate, and summarises previous work on the same lines carried out for the most part in Germany and America. In these rheumatoid cases various kinds of protein stimulation have been tried including veal protein, horse serum, the secondary proteoses of milk, and various bacillary vaccines. Dr. YEOMAN himself has come back to the antityphoid vaccine, introduced by ICHIKAWA 1912, using stock TAB vaccine for the reason t ample experience of the immediate and remote eff of this antigen has accumulated during the last 20 years. All observers seem to agree that little benefit is effected unless a sharp febrile reaction is obtained, the hyperthermia apparently having a direct stimulating effect on the formation of antibodies. With TAB vaccine skilfully applied a sharp febrile oscillation may be induced with a peak at 104° F. or above, followed by profuse perspiration, an early leukopenia giving place to a steep rise in the leucocyte count as the temperature falls. Some mental excitement and confusion may occur, but no other complications have attended the course of injections. A patient with experience of both regarded the TAB reaction as a trifle compared with the malarial chill. Immediate improvement was observed in 80 to 90 per cent. of all types of arthritis submitted to a course of TAB vaccine, the relief being maintained in 50 to 60 per cent. of the cases. Moreover, Dr. YEOMAN has been able to eliminate two groups of arthritics who do not respond, and so to limit the prospect of unsuccess. His results, it should be added, have been confirmed by other members of the staff of the hospital who have supplied him with cases for the purpose.

Into ophthalmic practice, too, protein shock therapy has lately been finding its way. In 1911 RÖMER used autohæmotherapy against gonorrhœal conjunctivitis, employing the principle, demonstrated by ECKART in 1894, that injected or transfused blood acts as a chemical stimulant. This reaction, to which WIDAL has attached the name colloidoclastic shock, includes a fall in blood pressure, leukopenia followed by leucocytosis, diminished viscosity, and delayed coagulation of the blood. In the latest edition of his text-book on diseases of the eye RÖMER records the experience of German ophthalmologists that protein injections may cut short the inflammatory reaction in gonorrhœal infection of the eye. Dr. H. F. SHORNEY,[1] ophthalmic surgeon to the Adelaide Hospital, now advocates cow's milk injected into the gluteal region, quoting German and Russian work in support. The technique is simple and the results encouraging. An important application has been found in gonococcal ophthalmia, but inflammation of the uveal tract has responded to the treatment, and Dr. SHORNEY believes that the use of milk injection will abolish the risk of sympathetic ophthalmia after perforating wounds of the globe. While it will not as a rule counteract panophthalmitis, it will generally avert the spread of infection after cataract extraction, when the wound has become infected. Dr. SHORNEY sterilises the milk by boiling for four to five minutes and injects from 2–15 c.cm., according to the patient's age, with a long needle. The temperature rises five to eight hours later. The dose is repeated next day if the reaction is insufficient, and on the fourth and fifth days in serious cases. The essential similarity between Dr. SHORNEY'S treatment and WAGNER-JAUREGG'S is obvious. Both inject a foreign substance with the object of producing a fever which stimulates the defensive mechanism of the body. Both are to be regarded, in the absence of more exact knowledge, as an elaborate protein-shock treatment. So long as physiologists can tell them so little about what actually happens, many clinicians may hesitate to employ such treatment except as a desperate measure, where all else has failed. We look to the biochemist to provide us with the knowledge by which the scope of this remedy may be defined and enlarged.

## SOCIAL HYGIENE AND PSYCHOLOGY.

THE annual general meeting of the British Social Hygiene Council was held on Wednesday, June 16th, Mr. E. B. Turner presiding. The annual report, which was adopted, reviewed the Imperial and medical aspects of the far-ranging work undertaken. The revenue account still shows a tiresome excess of expenditure over income, though substantial donations were received during the year ending March 31st, 1926, and grants towards administrative expenses were made by the Ministry of Health, the Colonial Office, and the London County Council. The reason for this is that under £500 were received in subscriptions, a position which does not reflect favourably on the generosity of the public, considering the many and great public benefits which can be traced directly or indirectly to the activities of the Council. When the report is able to show that the proportion of syphilis to gonorrhœa in the civil population is nearly approximating the proportion observed in groups of men under discipline in branches of the Services, we can realise what organisation is doing for civilian males, while there is no evidence that the incidence of gonorrhœa is higher among women than among men, despite the distressing existence of ophthalmia neonatorum. Earlier in the week Mr. Turner had presided over a conference of the Council, held at Leicester, to consider steps to be taken for the prevention of congenital syphilis, and urged that the Wassermann test should be applied to expectant mothers as a matter of routine and not necessarily at V.D. clinics. This suggestion was supported by Dr. Norman Cruickshank, who thought that an early blood test should be made always in obstetrical institutions, and the value of antenatal clinics in respect of the hereditary disease was pointed out by other prominent physicians. All this speaks clearly for the great value to the community of the Council's work.

The Council has issued the first number of its quarterly journal, *Health and Empire*, and only of recent years has it been possible for the problem of venereal disease to be frankly discussed as is done by the writers in this publication, who have no hesitation in coming to grips with reality. Mr. Cyril L. Burt, D.Sc., writing on the Contribution of Psychology to Social Hygiene, shows how the psychologist, quitting his books and his papers, now tests and analyses his fellow human beings and thus comes into relation with those intimate matters of individual life underlying the social problem that has led to the formation of the Social Hygiene Council. Dr. Burt points out that there is a notion that psychology has lately become engrossed in matters of sex, but he believes that it would be misleading to consider that particular set of social problems, to which the sex instinct has given rise, in separation from the rest. Mental mal-adjustment springs from abnormal sex relationships, but abnormal sex relationships may arise out of mental mal-adjustment. His position seems to be that, as a psychologist, he studies the workings of all the instincts, including that of sex, with the same untrammelled objectivity that science has, after much conflict, achieved in other spheres; and one must admit that an understanding of the problems of behaviour that complicate the control of venereal disease can scarcely be obtained by any other method of approach. He succeeds, moreover, in making clear the need for the psychological method in the study of social problems of whatever sort. Starting with the early influence of the home surroundings, he claims that, in both juvenile delinquency and those cases in which the breakdown is rather "nervous" than moral, an analysis of the mental history most often leads to a story of disturbed emotional relations with one or more members of the family. Any child who has not been a normal member of a normal household is likely to grow up gravely handicapped for future social life, and here he finds a profound reason for maintaining the integrity of the family as an essential factor in society. Mentally abnormal children he would class as the intellectually and the emotionally defective. The latter correspond partly with what are termed "moral imbeciles," and probably include a large proportion of future neurotics and lunatics, and certainly a considerable number of the most serious delinquents and incorrigible criminals, so that their early recognition is a necessary step of social hygiene. In juvenile delinquency Dr. Burt sees reactions arising from universal human instincts which cannot be stamped out or annihilated by summary attempts at suppression, but must be given rational and lawful outlets. The "moral sense" is not inherited but acquired, and there is no evidence that criminality or immorality as such is handed on by direct biological transmission. The mental defective cannot be cured, but the so-called moral defective very often can.

---

[1] Protein Therapy in Affections of the Eye. Med. Jour. of Australia, Feb. 13th, 1926.

The psychological investigation of an individual can succeed only if the subject has full confidence in the investigator, and a rule of technique is that the latter must express no moral judgments. The operation of cause and effect must, however, be freely recognised, and it is on these principles that Dr. Burt, when he comes to deal with prostitution, studies both the individual and the subject. He sees a change in the social tradition by which either the sex habits of women in the future will approximate to the sex habits of men in the past, or a new sex control among the men will approximate to the former self-restraint of women; but he believes that in the long run there will be a diminution in crude activities of a licentious kind and that prostitution as a mercenary calling will die out. There is a hopeful corollary to the psycho-analytical view that a vast number of wholesome social activities derive their strength from sex emotion; Dr. Burt believes that, just as society has, save for a few exceptional outbreaks, mastered the acquisitive and pugnacious instincts, so we must seek by a full and candid recognition of the sex instincts to direct their energy into other paths instead of trying to deny their existence or to trample them out. Whether Dr. Burt's views are fully accepted or not, the appearance of his article marks a recognition of the part that modern psychology plays in the understanding of some of the most perplexing social problems of the day, and it is to the credit of the British Social Hygiene Council that such large reflections should reach the public.

## HOSPITAL SUNDAY FUND.

Hospital Sunday falls to-morrow, June 27th, when in churches, chapels, and places of worship generally the congregations will be asked to recognise by their offerings the claims of the metropolitan voluntary institutions, the great hospitals, the lesser and special hospitals, and other domiciliary adjuncts to the treatment of the sick. The pecuniary needs of all these require no emphasising; despite the marked improvement of recent days in the incomes of certain of the larger voluntary establishments, an ever-pressing want of money is caused by a steadily rising call for assistance. The modern endeavour to avert and eliminate disease by preventive treatment has brought with it new burdens, and these burdens have been aggravated by the prevalent unrest in industry. The Metropolitan Hospital Sunday Fund has distributed among the charitable institutions of the metropolis over three millions sterling since its inception, and the cost for the collection and administration of this vast sum has been estimated at under 4 per cent.—a triumph of efficiency as well as a grand testimony to a huge mass of unpaid labour. And during the 54 years of the Fund's existence the scope of the hospitals has responded nobly to the wider demands upon them, for within their walls they have furnished to vast sections of the population treatment based upon the highest developments of medical science throughout a period which has been fruitful in the acquisition of knowledge and in its application.

# Annotations.

"Ne quid nimis."

## THE ANTI-CANCER CENTRES OF FRANCE.

Since the war France has made an effort on a considerable scale to deal more effectively with cancer among its population. Largely as the result of the efforts of the late Prof. Bergonié, anti-cancer centres have been formed with the threefold object of serving as foci of treatment, research, and teaching. Dr. Malcolm Donaldson and Prof. S. Russ, who recently visited the chief of these centres on behalf of the Medical Research Council, have made a report to the Radiology Committee of the Council from which it is possible to gauge the magnitude of this national effort and perhaps to draw some inference of its bearing upon that which other nations may feel impelled to undertake. There are seven anti-cancer centres in Paris and the immediate neighbourhood, and 11 in the provinces; the chief provincial centres are at Strasbourg, Lyon, Marseille, Montpellier, Toulouse, and Bordeaux, all of which were visited. Besides these centres there is the Centre Regional in Paris, presided over with such success by Prof. Regaud. The policy adopted at the provincial centres has been to construct new premises or make use of existing ones for the work in question and to appoint as director of the centre a surgeon, a radiologist, or a pathologist. The centres have all been supplied with radium, often in considerable quantities, and with X ray plant capable of giving penetrating radiation; in fact, special work in radiotherapy is being most energetically developed at these centres, as the chief therapeutic measure other than surgery. There is a close affiliation between the work of these centres and that of the Fondation Curie of the Institut Pasteur, of which Prof. Regaud is the director, and it is probably not too much to say that, though the inspiration for the formation of the centres came from Bergonié, the genius of Regaud is the main directing influence of the radiotherapeutic investigations being carried on all over France. The full results of this effort must be awaited, but it will surely make itself felt in the developments of new methods of radium therapy and in reducing cancer mortality. Clinical investigation in cancer cannot be hurried; the lapse of time is essential in evaluating the results of any therapeutic measure, but it can be helped by providing men and money. For the last four years the Medical Research Council has been carrying out such investigations at a number of medical centres; the results obtained seem to prove that, though radium is a valuable therapeutic agent in the treatment of cancer, its full potentialities are not yet developed. It may be that an effort on an even bigger scale will be necessary before a rigid determination of its utility is possible or before the technique is so standardised as to be made generally available to medical men throughout the country.

## LEAD POISONING FROM MOTOR SPIRIT.

Considerable attention has recently been paid in America to a new health hazard arising from the introduction of tetra-ethyl lead into petrol used in motor-cars. The lead contents escape, after explosion, with the exhaust gases in the form of fine lead dust. This liquid compound of lead is added to increase the explosive power of petrol vapour—a matter, fortunately for us, of greater importance for American than for British engines. Possibly here lies the reason why in this country we have not so far h to fac
the resulting hazard. Ethyl petrol,
first 1 part of tetra-ethyl lead to 1
later 1 part to 1300, was placed on s
in February, 1923. Serious cases of p
among men handling tetra-ethyl lea

petrol; hence its sale was voluntarily discontinued in May, 1925, awaiting the report of an expert committee. Careful and scientific investigations were undertaken in which car drivers using ordinary petrol were compared with drivers using the ethyl fluid, garage workers only handling ordinary petrol were compared with those handling the ethyl fluid, and all were compared with workers exposed to a known lead risk in factory employment. The text giving details of the inquiry, tables summarising the observations, and the report of the committee, have now been issued[1] by the United States Public Health Service. The report is reassuring inasmuch as no decisive clinical indications of lead poisoning due to ethyl fluid were brought to light, even though the garage men appeared to be absorbing definite small amounts of lead. Possibly these men experience a special exposure from the dust of garages, which was found to contain from 0·8 mg. to 22·3 mg. Pb per gramme of dust. The committee find no good grounds for prohibiting the use of ethyl motor spirit of a composition of 1 part to 1300, so long as its distribution and use are controlled. Immediately upon issue of this report tentative regulations for governing the manufacture, distribution, and use of tetra-ethyl lead have been submitted to the health officers of the various States for consideration, and they may be expected to be finally adopted at an early date. Meanwhile, we may hope that in this country the prevailing type of British motor engines will be maintained and that no need may arise for subjecting the public to a new and somewhat disconcerting health risk.

## STAPHYLOCOCCAL SEPTICÆMIA.

IN an interesting paper upon staphylococcal septicæmias which appears in a recent issue of the *Presse Médicale* (May 15th), Drs. P. George and H. Giroire, who have observed a number of cases of the condition during the last year, state that in most medical text-books two clinical types of this infection are recognised. First, a "typhoid" form, without special localisation in any organ, in which the diagnosis can only be made by blood culture, and secondly, a subacute form with pyæmic features. For their part the authors have met with two clinical types of generalised staphylococcal infection, in one of which the main localisation of the organisms is upon the heart valves, and, in the other, the infection is a facial one which they term the "erysipelatoid form." The first of the above types of the disease, which occurs principally in adults, commences with general symptoms and may be thought to be an influenzal infection, but the condition rapidly worsens and admission to hospital is usually sought in four or five days. At this time the patient is seriously ill and though splenic enlargement is present does not show any definite localising signs. There are, however, certain cutaneous alterations which the writers consider highly specific. These are of the nature of ecchymotic or petechial spots, which may occur over any part of the surface, and small bright red areas of about the size of a lentil situated especially upon the face and upon the extremities, which become vesicular and finally pustular and which upon bacteriological examination are found to contain staphylococci in pure culture. These are embolic lesions and sections show the capillaries of the underlying skin choked with masses of the organisms, whilst blood cultures give a pure growth of staphylococcus aureus. The patient progresses from bad to worse and death, which is often preceded by coma and hyperpyrexia, takes place usually within a week of the onset. At post mortem, examination shows the presence of an acute endocarditis usually involving the mitral valve alone and a certain number of embolic lesions in the lungs or internal organs. The authors consider that the symptomatology and the cutaneous lesions are characteristic and enable a definite diagnosis to be made prior to the results of blood culture being known. The lesion of the mitral valve is usually not sufficient to give rise to definite physical signs. The second clinical type here described which the infection may take is that in which, following upon a furuncle in the region of the bucco-nasal fold, a phlegmonous inflammation supervenes which involves on the affected side of the face the upper lip, nose, and orbital region. Severe general symptoms appear, blood culture is positive, exophthalmia may occur from involvement of the cavernous sinus, and death takes place within two or three days of the occurrence of general symptoms. This association of symptoms is termed by the writers the "erysipelatoid form" of the disease, chiefly on account of the diffuse inflammatory infiltration which develops around the primary site of infection, but its general resemblance to erysipelas seems but slight. At the same time the authors appear to imply that recognition of this condition as one of the forms which a staphylococcal infection may take has been wanting. This is certainly not the case, for in English surgical writing and teaching, and we can hardly think less so in France, the possible grave effects of a septic focus in the region of veins inosculating with the ophthalmics, and through them septic thrombosis, involving the cavernous sinus in the same process, is well known. The other condition of acute septicæmia associated with endocarditis is not as well known and does not seem to be a common occurrence in this country.

## INNOCENT AND MALIGNANT TUMOURS OF THE INTESTINE.

WHETHER or not the parenchyma of innocent tumours is more liable to develop malignant characters than non-neoplastic cells has long been a subject of debate among pathologists and surgeons. There is plenty of evidence to show that a carcinoma may develop in an adenoma, or a sarcoma in an innocent connective tissue tumour, but it is difficult to prove that the malignant cells are actually derived from those of the innocent neoplasm, that they are, as it were, a later stage in what is essentially a single process. It is common knowledge that innocent and malignant tumours frequently coexist side by side, but many authorities deny that this is more than a coincidence. And inasmuch as the vast majority of carcinòmata arise directly from epithelia without any intermediate adenomatous stage, it is clear that the assumption of malignant properties by the cell may be quite abrupt. One thing, however, is certain—namely, that the malignant process may originate simultaneously or nearly so in several parts of an epithelial area. It was demonstrated many years ago that an apparently single carcinoma of the tongue may in reality consist of a mingling of two or more independent and distinct tumours. Sir Lenthal Cheatle has demonstrated the same multiple origin in rodent ulcers, and a similar process has been shown to occur in the development of tar carcinomata in mice. Now Dr. Cuthbert Dukes analyses the same phenomenon,[1] this time as it occurs in the large intestine. For a long time it has been recognised that simple tumours of the mucosa of the large bowel are often followed by the development of carcinomata; especially in this prone to occur when the intestine is the seat of multiple papillomata. Dr. Dukes has made an extensive and careful study of these lesions, and has brought to light some very interesting points. In the complete large intestines of 127 persons dying from diseases other than cancer, single or multiple adenomata were found in 12 cases (rather less than 10 per cent.), but in 33 successive intestines affected with carcinoma such adenomata occurred in 25, or 75 per cent. Inasmuch as in the malignant cases only the small portion of intestine removed along with the tumour by operation was examined, the difference is even greater than would appear. Investigating these tumours anatomically, Dr. Dukes finds that in the early stages they are usually multiple, though fusion of neighbouring foci of proliferation may in the later stages give rise to an apparently single growth. Moreover, at the margin or neck of the adenoma the adjacent epithelium presents pronounced chronic inflammatory changes. In course of time malignancy supervenes in these irritated cells, as well as in the cells of the adenoma itself. Dr. Dukes suggests that a cancrogenic agent causes a more than usually vigorous growth in many separated spots in a considerable area of mucous membrane. Later, a crop of adenomata arise from this sensitive field, and some of these become surrounded by secondary tumours. The mucosa between these primary and secondary tumours becomes irritated, hampered in its growth, and folded inwards. Whether the malignant change develops in these dislocated cells or whether in the cells of the actual adenomata is uncertain, but the cancer makes its appearance when a crop of simple tumours has arisen in an irritated field and in close association with one of them. The author's conclusions are supported by excellent figures and diagrams, and his article is as convincing as it is interesting.

## RESEARCH IN BREWING

BREWING, like the agriculture of to-day and the medicine of yesterday, is one of those ancient crafts which the patient labour of the scientific investigator is slowly raising from the status of an empirical art to that of a science. It is to the credit of the brewing trade, at a time when many industries are accepting or seeking help from some outside source, that its own Institute has financed a research scheme by a system of voluntary contributions based on output from nearly 300 firms. Results of considerable technical and scientific value appear in the fifth annual report of the Institute of Brewing Research Scheme, covering the period April, 1924, to April, 1926, which has just been issued. Beer needs for its manufacture four main ingredients—water, barley malt, hops, and yeast—and each of these materials forms the chief subject-matter for investigation by the four subcommittees of experts. Until the Institute shall have appointed a director-general of research the chairman of the Research Fund Committee, Mr. J. S. Ford, F.R.S.E., is acting in that capacity. Field experiments, carried on all over England on the influence of soil, season, and manures on the yield and quality of barley grown for malting, are supervised by Sir John Russell, F.R S., director of the Rothamsted Experimental Station. After malting the analytical work is in the hands of Mr. H. Lloyd Hind, whose results promise well for both farmer and brewer. Investigations on hops comprise the systematic breeding and crossing of new varieties at the South-Eastern Agricultural College, Wye, by Prof. E. S. Salmon, and their testing at the East Malling Research Station and at Horsmonden. The objects in view are to procure for the grower new and prolific varieties of hop more able to resist disease, while at the same time securing for the brewer the qualities he considers valuable. Chemical investigations on the preservative and antiseptic properties of hops have engaged the attention of Prof. F. L. Pyman, F.R S., and Dr. T. K. Walker at Manchester since 1921. It may not be generally known that apart from the agreeable flavour conferred on beer by hops, they are a valuable ally to the brewer in his fight against the invasion of his beer by the foreign organisms which cause turbidity, fret and acidity. Valuable work is being done on the keeping properties of the yeast used for fermentation and the effect of hydrogen-ion concentration on the character and stability of beer. The measurement of the true "free acidity" is becoming recognised as an essential procedure in the various stages of brewing. Over and above the actual staff of the Institute a large body of farmers, brewers, chemists, maltsters, and hop-growers—all busy men—voluntarily give their services on numerous committees supervising the researches, while expert technical assistance is engaged where required. It should not be forgotten that it was on the basis of Pasteur's researches on the disease organisms of wine and beer that arose the superstructure of modern surgery and preventive medicine.

## FLUORINE AS A SLOW POISON.

THE toxic effects of long-continued small doses of iodine and bromine and their derivatives are well known. Recently Prof. H. Cristiani has described[1] chronic poisoning by another member of the halogen series, fluorine. This element is apparently present in minute quantities in many of our foodstuffs, and was at one time frequently used as a preservative, although its use as such is now prohibited in most countries. In the neighbourhood of certain factories the food of animals may contain toxic quantities of fluorine, and this element may also be present in excess in water into which certain industrial products have been allowed to pass. In some districts in Switzerland where these conditions are present an endemic disease occurs among animals, characterised by wasting and cachexia, with a special localisation in the regions of the vertebral column and lower limbs, while the bones become softened and frequently show spontaneous fractures. On account of this last symptom the disease has usually been considered by veterinarians as a form of osteomalacia, and farmers and others seeking compensation for their diseased cattle have been met by the statement that there is no evidence that osteomalacia can be caused by the ingestion of poisonous substances. Prof. Cristiani has set himself to disprove this, and he has established that the disease from which these animals suffer can be separated from true osteomalacia and should be designated by a separate name such as "fluorism" or "fluorine cachexia." His experiments consisted in feeding animals on diets which, while maintaining perfect health in control animals, produced the syndrome described above when there was added in small doses (*a*) hay which was suspected of having produced the disease in cattle; (*b*) hay mildly impregnated with certain salts of fluorine, or (*c*) grass submitted to the action of fluorine in one of its gaseous forms and used either fresh or as hay. The time of appearance of symptoms was variable and depended to a certain extent on the dose of fluorine employed. The experimental animals wasted and eventually died with symptoms of bulbar paralysis and respiratory failure. At autopsy the bone-marrow was found to be extremely scanty; the bone-tissue showed much rarefaction, and the bones on analysis showed a high fluorine content. Prof. Cristiani is at present studying the question as to whether chronic fluorine poisoning occurs in man. Its symptoms are so slow in appearing and in progressing that it may possibly be present sometimes among the inhabitants of industrial areas where much fluorine is produced.

## THE PATHOLOGY OF BURNS.

THERE was for a long time a good deal of difficulty in explaining the toxæmia and death which may follow burns, and it is only comparatively recently that our knowledge of the subject has determined to a satisfactory explanation which brings the ill effects of burns into line with the shock due to tissue injury. The evidence, along with an interesting discussion of burns of all kinds, is well summarised by Dr. G. T. Pack in the *Archives of Pathology and Laboratory Medicine* (1926, i., 767). In the first place, it is clear that the poisonous substance comes from the burned tissue and is carried in the blood; if the tissue is excised toxæmia is prevented, and if burned skin is t
planted from one animal to another the lat
symptoms and dies. If one of a pair of
Siamese twins is burned, both have
experiments with crossed circulatior

---

[1] La Presse Médicale, April 14th.

animal which is poisoned is the one in which the blood from the burned tissue circulates and not the one of which the burned tissue forms a part. In the second place, it has been shown that the poison is not generated in the process of burning but subsequently. Symptoms in man do not appear till, perhaps, 24 hours after the actual burning, and if parabiotic twin animals are separated within 12 hours after one has been burned the other does not develop symptoms. The facts are strikingly in accord with those by which Cannon, Dale, and others have shown that secondary shock is due to the absorption of histamine and similar bodies which arise in the disintegration of smashed-up tissues. They also give a satisfactory explanation of why the danger of a burn depends more on its surface area than its severity. The poisonous products of autolysis do not come from the tissues which are thoroughly destroyed—charring or anything near it breaks them up beyond the possibility of that—but from the tissues in the next zone where the cells are killed by heat but not actually burned. These dead cells autolyse and break up; this takes some time and explains the delay in the onset of symptoms. And it is evident that a severe carbonising burn does not necessarily produce more dead cells capable of a poisonous autolysis than a comparatively superficial lesion of the same surface area. The dangerous tissues are those which have been heated just enough to kill them without destroying the autolytic ferments or causing much chemical decomposition.

## THE ROYAL SOCIETY CONVERSAZIONE.

The deferred annual conversazione given by the Royal Society was held at Burlington House on June 16th, when leading scientists took the opportunity offered to display the results of their investigations, and a very large circle of interested visitors was enabled to gain an insight into recent developments of scientific inquiry. The majority of the exhibits shown on this occasion related to problems in physics, some of them of direct interest to radiologists. Prof. O. W. Richardson showed an apparatus for the investigation of soft X rays varying in wave-length from about 20 to 400 Angström units. For this purpose a highly exhausted X ray tube of transparent silica was excited by constant potentials of from 300 to 600 volts. Owing to the low penetrating power of the rays produced by these voltages, the means for measuring them was incorporated in the tube. A series of photographs of $\beta$ ray tracks produced by X rays in different gases was shown by physicists of Victoria University, Manchester. These tracks may be divided roughly into two groups according to their length. The long tracks are due to electrons ejected from atoms which have absorbed a quantum of X rays, whilst the short ones are supposed to accompany the process of scattering by matter. Of these two phenomena the latter is of more importance in light gases and is one which will probably engage the attention of radiologists in the near future. Radiography was represented by a series of plates taken at the Royal Arsenal, Woolwich. A radiograph showing a cavity 0·3 in. wide in a piece of steel 4½ in. thick, served to illustrate the high penetrating power of the X rays which may now be produced and of the differentiation in density which is possible with them. A number of electrical instruments for physiological research were shown by Mr. A. C. Downing, who has determined the heat values for muscle and nerve actuated by a variety of stimuli. An exhibit of Mr. T. S. P. Strangeways and Dr. H. B. Fell marks an advance in tissue culture, shown by the development in vitro of the isolated eye of the embryonic fowl. For these experiments one eye dissected out from a fowl embryo of 64 to 70 hours' incubation was explanted into a medium composed of fowl plasma and embryonic tissue extract, whilst the other eye served as a control. The specimens exhibited showed the growth of the lens, the formation of pigment, the differentiation of the iris and the development of the reticular, ganglion cells, nuclear and "rods and cones" layer of the retina. The eyes under cultivation were thus seen to grow in a surprisingly normal manner. Of historical interest was an early microscope of the Leeuwenhoek type and possibly the only example of its kind in England. The instrument was made by Butterfield, who, in 1678, communicated to the Royal Society a paper on the Making of Microscopes with Small Single Glasses. The instrument shown was made of silver and consisted of one lens and a movable pair of forceps for supporting the specimen under observation. A microscope of this type was used by Leeuwenhoek for most of his classical work.

## BELATED HOSPITAL REPORTS.

It is an old complaint that Government reports and statistics are published so long after the dates to which they refer that their usefulness is much diminished. Similar disabilities are inflicted in full measure upon those who, of necessity or from inclination, are concerned with hospital affairs and hospital figures. A few days hence the first half of 1926 will have passed, yet we are still receiving hospital reports for the year ending Dec. 31st, 1925, provincial newspapers are still reporting belated annual meetings, and similar things will happen for some time to come. We are well aware that hospital staffs, medical and lay, are always pressed with work; but an annual report is part of that work, and it is not more arduous to undertake it in January than in March or April, or even later. It cannot often chance that important material is unavailable for many weeks or several months after the end of the year, and we are quite sure that it is difficult to avoid languor and weariness when dealing with facts and figures which lapse of time has robbed of their freshness. Moreover, the student of these reports and statistics has an uneasy sense that he is conning ancient history and that his reflections and conclusions may be to a greater or less extent vitiated by delay and the emergence of new circumstances. Once upon a time these delays were of comparatively small moment, but to-day hospitals are the most outstanding fact in the domain of public health. They are watched more carefully than ever before; since the war the number of people interested in their individual fortunes and in the voluntary system generally has enormously increased, and it would seem to be only businesslike prudence to publish the results of their year's work as speedily as possible. The reports issued by many of the larger hospitals are volumes of real scientific, social, and statistical importance, and it is much to be regretted that information of obvious comparative value should be withheld both from specialists and the general public until it is growing stale and, perhaps, halfway towards being superseded by later experience.

---

Glasgow Royal Infirmary Auxiliary Hospital. The pressure upon the wards and the long waiting list have made it imperative that an auxilliary hospital should be established at an early date. Some time ago Mr. James Macfarlane, the chairman of the board, and his brother, Mr. George W. Macfarlane, provided a site of 22 acres at Canniesburn, some five or six miles outside the city. The trustees of a recently deceased testator have now given £10,000 to the cost of building; a similar sum was given last year by Miss Margaret Clarke, the daughter of a former Glasgow physician.

A Garden Home for Pre-tuberculous Children. The Liverpool Hospital for Consumption will shortly open at Frankley, in Cheshire, a garden home, with 40 beds, in 18 acres of land, for pre-tuberculous children. It is hoped later on to extend the home considerably, as 150 beds are needed for Liverpool alone, apart from those required for Cheshire. During the past year a nurses' home has been built in Delamere Forest, separate from the sanatorium there. Dr. H. A. Clarke has just retired from the active medical staff of the hospital after 33 years' service, and has been appointed consulting physician.

### *After-treatment.*

In the period immediately following operation the Fowler sitting position is essential, abundant fluid by rectum necessary, and starvation by mouth of the greatest use. Having got the patient through his crisis, let him have bodily and mental and visceral rest. If thirst can be really controlled by proctoclysis not even fluids need be given by mouth for 24 hours, but in the absence of vomiting small drinks bring great relief to the patient and need not be withheld.

Subsequent feeding must depend upon the general condition. In feeble patients begin with clear fluids at the end of 24 hours. In vigorous patients give only water by mouth for 48 hours. Glucose (5 per cent.) in the rectal saline is always useful. Morphia, gr. ⅙–¼, is indicated for the first night, but is not usually required again. Nothing but clear fluids (albumin-water, weak tea, raisin tea, beef juice) are given for four days; on the fifth citrated milk may be added, and by the seventh a little bread-and-butter, milk pudding, or Benger's food can be given. On the ninth day the patient gets pounded fish and a lightly boiled egg. An enema on the third day or earlier may bring relief from flatulence, and a weak aperient, such as inf. sennæ ℥ss., is ordered on the fourth day. Convalescence is usually smooth if the patient rallies from his shock and survives the first few days. Later, subphrenic abscesses or a hæmatemesis may occur, and in this event patients mostly succumb in the end.

### *Conclusion.*

Simple suture will cure permanently at least one-half of those patients who survive. It is time to talk of further operative measures when several months have elapsed, should symptoms of indigestion still persist.

## THE HEALTH OF THE NAVY IN 1923.

THE Statistical Report of the Health of the Navy for the year 1923, just published by H.M. Stationery Office (pp. 149, 5s.), shows an improved standard of health. Compared with the preceding year, there were fewer cases of illness, fewer accidents, fewer deaths, fewer invalidings, and fewer men daily on the sick list. The appended table shows the distribution of the casualties.

In 1923 there was a reduction of about 8000 in the total naval establishment, which falls readily into three great groups—viz., the Atlantic Fleets, the fleets abroad, and the Home Station, the latter including recruits, men under training, and those awaiting discharge. For some reason unexplained the 3710 marines at headquarters are separated off from the 89,100 other men in the Service, who are called the Total Force. The death-rate was 2·9 per 1000 in the fleets abroad and 1·4 in the Atlantic Fleet. There were 38 deaths from injuries and accidents, 18 from drowning, 17 from tubercle, 15 from diseases of the intestines, 13 from suicide, 12 from pneumonia, 11 from heart disease; the total of deaths was 194—2·17 per 1000. The invalidings were, in order of magnitude, as follow: diseases of the eye, 200; diseases of the ear, 158; gonorrhœa, 151; tuberculosis, 143 (50 less than in 1922); neurasthenia, 101; heart diseases, 86; and injuries, 56. In all there were 16·08 per 1000 invalided, a reduction of 20 per cent. in the year. To judge from the curve of actual invalidings the reduction was most marked at the younger ages and in the earlier years of service. This suggests more careful recruiting or better care of the recruit, or both. The Blue-book records events, without stopping to explain the reason for them, but it appears that the benefit is now being reached of the long campaign for better ventilation, for not only are pneumonia and tuberculosis decreased, but also respiratory diseases, such as catarrh, bronchitis, and pleurisy.

Vaccinations and revaccinations to the number of 23,000 are mentioned, which makes it the more difficult to understand how an officer who contracted small-pox at Smyrna had managed to escape revaccination all his time in the Service. There were but 803 cases of influenza in 1923, epidemic only in ships in Australia and New Zealand; in 1922 there were 4514 cases, of which the maximum, 1837, was in the

Atlantic Fleet. Malaria is lessened this year, which on the East Indies Station, is perhaps to be associated with the fumigation of all ships on completion of their annual refit at Bombay One case was invalided for frequent recurrence of blackwater fever There were three apparently quite unrelated cases of meningococcal infection Tuberculosis has decreased remarkably, case, invaliding, and death rates per 1000 being 1 80, 1·00, 0 19, as against 2 26, 1 09, 0 37 in 1022 The attack rate of the sick berth staff is again reduced, now to 2 07 The rate of 4 55 among telegraphists causes question, their cases being distributed over nearly all the stations Infection is believed to have been limited at Hong Kong by disinfecting boats with formalin after their refits, lest infection may have been left behind by spitting dockyard labourers, a promising line of advance. Marines at headquarters seem to have only half the liability (1 9) they manifest on ships (3 31) As this year there are fewer cases of gonorrhœa, the total incidence of venereal disease is reduced, and, as usual, there is least among marines at headquarters It is more prevalent abroad, especially in China. The further results of the closing of brothels in Gibraltar are unmentioned "The great majority of the infections have been contracted by men under the influence of alcohol" is an opinion from China. Two deaths from cholera are reported and one from (clinical) relapsing fever In regard to the latter it does not appear that blood films were sent home for confirmatory opinion. Diseases of teeth and gums, of mouth and pharynx, continue to decrease, much attention has been given to dental repair, two thirds of the defective teeth are being conserved, and only one-third extracted. Cases of scabies are fewer and each a shorter time under treatment. Malignant new growths are also fewer

*No statement is made* of health conditions among cadets at Dartmouth. There are fewer boys under training; their pneumonia rate is reduced and their tuberculosis rate is identical, rather below that of the rest of the Service—3 cases of pneumonia, 3 cases of tuberculosis among 1700 boys. The Admiralty might very well publish fuller information *about the feeding and management* of these boys; it would be welcomed by those in charge of schools

# INDIAN MEDICAL SERVICE

## ANNUAL DINNER

EIGHTY-ONE officers of the Indian Medical Service sat down to the annual dinner at the Trocadero, London, on June 10th. Lieut Colonel R. H Elliot, D Sc., F.R C S, was in the chair, and the guests were Sir Richard Luce, Sir Dawson Williams, and Dr E C Morland The other members of the Service present were as follows —

Major-Generals: Sir R. H. Charles G C.V O K C.S.I B. R. Deare, C.I.E.; T Grainger C.B., G F A. Harris C.S.I., H. Hendley, C.S.I. J B Smith, C.B. C.I E.

Air Vice-Marshal: D Munro, C.B., C.I E.

Colonels J Crimmin, V C C B C.I E., C. M. Goodbody C.I E., D.S.O T A. Granger C.M.G. C. R. M. Green; J A. Hamilton C.M.G, R. A Needham C I E. D.S.O; J J Pratt, H Austin Smith, C.I.E. T Stodart, C.I E., P C. H Strickland R. G Turner C.M.G D.S.O C N C. Wimberley, C.M.G

Lieut.-Colonels: A. W Alcock, C.I.E., F R.S W G P Alpin, O B E., J Anderson, C.I E., L. A P Anderson R. W Anthony, J. T Calvert, C.I.E. R. Markham Carter C.B. Captains S. L. Bhatia M.C., J H. Grove-White

# PARIS

(FROM OUR OWN CORRESPONDENT)

### *The Campaign against Alcoholism*

FOR some time past the Academy of Medicine has been preoccupied with the national danger resulting from a recrudescence of alcoholism, and a Commission has been studying the various measures which might be taken to prevent it. *Prof Marcel Labbé* submitted the following resolutions which were adopted and transmitted to the proper authorities The anti-alcoholic regulations of the war should remain in force and be vigorously applied The law in regard to absinthe substitutes should be revised and strictly applied The number of places where alcoholic liquors *are sold should be limited*, the *application of this* measure being facilitated by social ameliorations such as healthy housing construction for the workers and the creation of places of popular recreation The use of grapes as food and of non fermented grape juice should be popularised as well as the industrial utilisation of alcohol Anti alcoholic education should be *organised in all classes of society Other resolutions* are being studied amongst them the question of home distillation, of increasing the duties on alcoholic liquors, and of creating houses of entertainment where only non alcoholic liquors can be consumed.

### *Indemnities for Hospital Personnel*

As I have already remarked, no protection has heretofore been provided against infection or accident incurred by the medical or nursing staff when on duty in hospital Nearly every other kind of *occupation is provided for, either by the law of* 1898 or by new clauses added to it since. In view of several recent deaths among internes at Paris hospitals, the Minister of Labour is promoting legislation to extend the application to hospital personnel so that, for example, disability of 100 per cent. would entitle to a pension of 9706 frs. The widow of a deceased *member of the staff would receive annually* 2912 frs; one child would be allotted 2184 frs. two children 3640 frs, three children 5096 frs., and four children 5825 frs In the absence of widow or children the father and mother of the deceased would receive 2912 frs annually Such in outline are the lines of the provisions being urged by the Minister of Labour which will undoubtedly be *realised very soon.*

### *Arsenic in Puerperal Infection*

Dr Maurice Rivière, professor of clinical obstetrics at Bordeaux, *is employing organic salts of arsenic* for puerperal infection, whether syphilitic or not, and advises this method to the exclusion of any other, especially fixation abscess He finds that arsenical injection generally suffices to avoid complications and to limit infection In practice sulfarsenol is preferred, a subcutaneous injection of 0 12 g repeated at need *every other day up to a total of five or six injections* In some cases the dose is increased to 0 18 g Intravenous injection is reserved for grave forms of disease or those in which the usual methods of treatment have been tried and failed. The medication is said to have been equally efficacious in cutting short an attack of phlegmasia alba dolens.

### *Ovarian Grafts in Psychopathic Conditions*

Dr Toulouse, director of the mental prophylactic service at the Asile St Anne has been trying ovarian *homografts in two cases of melancholia* and in six cases of catatonic syndrome The grafts were obtained from women who had undergone operation for hæmorrhagic fibroma and they were inserted beneath the skin of the patient In the two melancholic cases and in two cases of dementia præcox a notable improvement followed which persisted. The first results are only regarded *as an indication for further investigation* The graft has survived in favourable cases for from 1–1½ years and at the worst it survived 14–21 days. In one of the patients who was considered cured some slight evidence of relapse in the mental condition has since been noted.

### *Horse Serum as Wound Dressing.*

Horse serum has often been used in the treatment of wounds, particularly to accelerate the healing of ulcerated surfaces. Dr. G.-A. Weill (Paris) now suggests its employment to replace collodion, since in drying off it forms in a few minutes a varnish which adheres closely to the integument, with the further advantage of dissolving rapidly in warm water. Dr. Weill suggests that horse serum may thus replace bandage, collodion, or leucoplast in wounds of the face, hands, and fingers. The dressing is light and practically invisible; a little wool or gauze soaked in the serum is spread over the wound, and on the film when it is nearly dry boric acid is powdered to permit of the glove or other clothing slipping smoothly over the dressing. Horse serum is more adherent than collodion and has not the inconvenience of being retractile.

### *International Sanitary Conference.*

A conference, which has been sitting in Paris for some weeks past, is endeavouring to harmonise international views on certain questions of sanitation, mostly of maritime interest. Recent knowledge of incubation periods, modes of infection, and such matters have rendered modifications desirable in various aspects of maritime quarantine. The inspection of immigrants is being carefully considered. Representatives of various governments are attempting a revision of the international conventions now in force.

### *The Death of Prof. Teissier.*

Louis-Joseph Teissier, who has just died in Lyon in his seventy-fifth year, had, since 1878, filled the chair of clinical medicine in the Faculty of Medicine at Lyon, where he was a member of the Academy and administrator of the civil hospitals. In 1908 he was elected national associate of the Academy of Medicine. His scientific works include papers on aneurysm of the aorta, public and social hygiene, pathogeny of influenza and albuminuria, and last but not least a treatise on internal pathology, in collaboration with Laveran, which has rendered great service to successive generations of medical students.

### *Post-graduate Courses.*

Several new post-graduate courses were inaugurated this year at the Faculty of Medicine and in the various hospitals of Paris. The course in urology at the Hôpital Necker, which has just closed, was attended by some 30 students from England, Canada, the United States, and several South American countries. Prof. Lemaître, in charge of the course in plastic surgery, has secured the coöperation of English-speaking surgeons who lecture and demonstrate in turn. Among those who have presided at the classes are Prof. Conrad Smith, of Boston, Prof. C. G. Coakley and Dr. J. E. Sheehan, of New York, and surgeons from England, Ireland, and Canada will take part. This course is really of international scope.

### *Severe Electric Burn.*

In a case observed by Dr. Gelas, in which massive burn of the entire arm required shoulder disarticulation, all the tissues were found to be coagulated. Healing required 15 months, for six months of which an afebrile tachycardia was present. The rectal drop method of administering glucose solution proved helpful in this case. Dr. Gelas remarks that in such cases antiseptics are to be avoided, vaseline or ambrine being used. Operation should follow the burn promptly to prevent absorption of the toxic substances which are formed.

The Aid Society for Physicians' Widows and Children has just adopted two children whose fathers were physicians, and will care for and educate the children until they are 21 years old.

The Abbé Tauleigne, whose death is announced from Pontigny, collaborated with Ducretet and Roger in a number of X ray inventions. He fell a victim to his investigations and received from the Carnegie Foundation in 1923 a silver medal and the sum of 5000 frs. He was 56 years of age.

At a recent council meeting of the French National League against the Venereal Peril, Prof. Jeanselme was unanimously elected honorary president. Dr. Queyrat spoke to the importance of dispensaries and laboratories in combating syphilis, and the Council approved the purchase of land upon which will be erected a central serologic laboratory.

The thirteenth annual hygienic congress is to be held at the Pasteur Institute in Paris from Oct. 19th–21st. The agenda includes a consideration of: 1. Sanitary aspects of immigration. 2. Preservation of food by cold. 3. The functions of sanitary inspectors and bureau chiefs in combating tuberculosis, and a discussion, to be introduced by Dr. Louis Martin, on the measures employed in combating diphtheria. Anyone wishing to read a paper or to attend the congress should apply to Mr. Bossus, 142, Boulevard du Montparnasse, Paris, 14e.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

### *Public Health in Bihar and Orissa.*

AT the 1921 census the population of this province was about 34,000,000, exclusive of the tributary States of Orissa. During 1924 the birth-rate was 35·7 per 1000, as compared with 37·0 in the previous year, and Lieut.-Colonel Ross, in his annual report for the year, remarks that the steady rise of the previous three years has reached its maximum and that the rate is now falling again owing to "discontinuance of the favourable conditions" (which are, unfortunately, not specified). The birth-rate in the districts varied from 26·6 in Purnea to 45·9 in Palaman, and in some of the towns it was as low as 11·8. The death-rate rose from 25 to 29·1, which increase was due partly to climatic conditions and partly to a widespread outbreak of cholera; in the previous decennium, however, the annual average was 34·1. Here, again, there was great variation; in the Singbhum district of Chota Nagpur the mortality was only 16·3, whereas in Cuttack it was 44·1, and such differences cannot but draw suspicion on the accuracy of the statistics. In the different sections of the community the death-rate was 30·9 amongst Hindus, 26·4 amongst Mohammedans, 13·1 amongst Christians, and 22·7 in the "other classes." The general infantile mortality was 158·4 per 1000 births, as compared with 146·5 in 1923; for rural areas the rate was 157·9 and for towns 178·6.

Infectious diseases are naturally more prevalent in the towns, whilst malaria is more prevalent in the rural areas where there are more mosquitoes and economic conditions are often not so good. "The large towns," says Colonel Ross, "are hot-beds of consumption," and respiratory diseases cause far more deaths in town than country. Throughout the province there was a considerable increase in cholera, the death-rate being 2·2 per 1000, as against 0·2 in 1923. Only one district, and that a small one, returned no deaths, and in some of them the death-rate rose to 6·6. Active measures were taken against the disease. Chlorinated lime for well disinfection "has now been generally adopted by local bodies and the procedure is generally known and appreciated." The epidemic cadre of ten assistant surgeons was maintained throughout the year, and a special staff of 20 doctors was employed during the epidemic prevalence, from April to September; also an epidemic reserve of 200 vaccinators was maintained during this period.

"After careful trials kaolin has been introduced as the most suitable treatment for general issue throughout the province, both because it is a valuable remedy, and also because it does not deteriorate when stored, and can be safely entrusted to laymen for distribution; it is both cheap and effective. . . . In previous severe epidemics the total mortality has amounted to from 150,000 to 200,000: in this epidemic the deaths numbered 77,480, although the epidemic was prolonged and very widespread. The figures speak for themselves."

There was a further reduction in mortality from plague (0·8 per 1000, as compared with 0·8 in 1923 and 0·9 for the decennial average), and the disease appears to be slowly diminishing in virulence and prevalence with the lapse of time. Dysentery and diarrhœa caused 26,575 deaths. "The prevalence," says Colonel Ross, "is probably associated with the climatic conditions, and is to a large extent due to the bad state of the water-supply in many parts of this division." It is satisfactory to learn that "the work and usefulness of the school medical officers is gradually becoming better known and more appreciated; and there is every prospect of success in what was at first purely an experiment." The general health of the prisoners in the jails was satisfactory, the average population numbering 6276, of whom 5345 were convicts.

### *The Medical Profession in India.*

An account of the presidential address by Colonel Raghavendra Row, I.M.S., to the Indian Science Congress appeared in THE LANCET of May 22nd (p. 009). The address contained much adverse criticism of the medical profession in India at the present time and has aroused some opposition. At a recent meeting of the Bombay Medical Union the following resolution was passed:—

> "The general meeting of the Bombay Medical Union has considered the presidential address of Dr. R. Row, delivered at the Science Congress this year. It appreciates the efforts of Dr. Row to stimulate the growth of research workers amongst us, but is constrained to express its opinion that the tone and spirit of the address is to overestimate the value of I.M.S., and underrate the Indian medical profession. The allegations made against the Indian medical profession under the heading of 'Statement' said to be furnished by an anonymous I.M.S. man are nothing short of calumny and require to be repudiated by him in fairness and justice to the Indian medical profession to which he belongs. The Union regrets that some of the remarks made by him about the state of affairs of the independent medical profession are not justifiable and are detrimental to their interest leaving aside his exalted views about the I.M.S. as a whole, and from which the Union begs to differ."

### *Poisoning.*

The report for 1924 of the Chemical Examiner, Madras, records an increase of medico-legal work. No less than 234 cases of suspected human poisoning were examined during the year; poison was detected in 100 cases, and as a result of these 100 cases 189 persons were affected and 69 died. The commonest poisons were opium (19 cases) and arsenic and mercury (18 cases each); aconite, atropine, and strychnine were also commonly used. Apparently a larger number of dhatura cases were dealt with than usual, and the Examiner suggests that there must have been a small gang or society of professional poisoners at work. This view is supported by the skill with which the poisoners introduced the drug into the food of intended victims, judging the dose so that their subject was rendered unconscious but not killed. In several instances poisons, such as opium, mercury, and strychnine, were given in arrack, but this medium was usually unsatisfactory, as in most cases the vomiting which immediately sets in seemed to have saved the lives of the victims.

Stains and blood have to be examined frequently and from time to time love philtres are sent for investigation. One of them was in an unusual form in that it was designed for external application and consisted of an oily liquid to be rubbed on the head. This departure from precedent, however, seems to have been worse than useless, since the woman to whom it was applied, so far from conceiving an affection for her lover, ran him in for damages for the mental and physical injuries which the philtre, she said, had caused.

At the request of the Jail Department, the Chemical Examiner carried out research on the effect of tamarind juice and curry on zinc vessels. It was found that these substitutes corroded the zinc if left in contact with it for 24 hours, and that the zinc could be detected in the curry or juice. Zinc vessels have, however, been used in the jails of the Bombay Presidency for several years without any cases of zinc poisoning being reported.

---

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Housing Shortage and Mental Diseases.*

THE housing shortage has been very prejudicial to the health of the population in Germany. Not only have tuberculosis and other infectious diseases been more widespread but the psycho-neurotics among the population have been adversely affected by the difficulties of securing adequate accommodation. Dr. Bernhard stated recently at a meeting of the Berlin Forensic Society that unstable people who had to appear before the housing authorities often came in a state of irritation and with a tendency to commit violent acts. People without energy became unduly depressed and were liable to fits of hysterics when the accommodation granted to them did not meet their wants. The magistrates had often to deal with such people. The decisions of the housing authorities had sometimes led to severe consequences. For example, a seamstress who had been compelled to give up part of her lodging to another party suffered under the delusion that she was being poisoned by them, that they had done wilful damage to the property, and that she was being persecuted by them. She brought an action, causing much trouble to the authorities. In another still more serious case three families had to live together within a small flat. After a dispute one of the tenants shot two others in a fit of mania. A similar case was reported from Frankfort where also a psychopathic tenant had killed two of his fellow tenants. All these cases occurred in people who before the war had occupied a flat of their own and had not been accustomed to share their rooms with other people, sometimes of a different class. Dr. Bernhard was of opinion that in doubtful cases the housing authorities should collaborate with the medical officers of health to inquire into the mental state of those who were to be billeted together.

### *The Dangers of Amalgam-fillings.*

Prof. A. Stock, head of the Institute for Applied Chemistry, has drawn attention to the fact that amalgam-fillings of the teeth may cause mercury poisoning. The Berlin Dental Society has recently discussed the question. Prof. Stock said that severe mercury poisoning, formerly so frequent in workmen, has now become very rare owing to the progress of industrial hygiene; it is thus nearly unknown to the present medical generation. He had himself suffered for many years from chronic catarrh of the nose and the oral cavity for which he consulted several specialists without success. Some time ago it was discovered that the air in his working laboratory contained a minimal quantity of mercury vapour, sufficient, however, to produce symptoms of poisoning in him if inhaled over a long period. Obviously he had an idiosyncrasy against mercury and he was therefore advised by a toxicologist to have his amalgam-fillings removed. When this had been done the symptoms, which had existed for many years, disappeared. He accordingly examined whether amalgam-fillings may indeed give off mercury, and discovered that old fillings give off a small quantity of mercury, while in fresh and defective fillings the quantity is larger. By experiment he ascertained that the air inspired by a man whose teeth had been filled three years before contained mercury. He suggested that medical men, especially those working in throat and nose diseases, should consider whether in an obstinate catarrh the symptoms might not be caused by defective amalgam-fillings. The discussion which followed his address was very animated. Prof. W. Dieck, of the Dental Institute of Berlin University, stated that the d
of amalgam-fillings were known long ago
they were present only so long as the fillin
been entirely hardened. He warned

attempt to generalise from Prof. Stock's own case; he obviously had a special idiosyncrasy to mercury, since even the minimal quantity of mercury in the air of his laboratory had a prejudicial influence on his health. Prof. Schultz was of opinion that medical men should carefully avoid suggestion in taking the clinical history of neurasthenic people who are apt to show symptoms of poisoning if their attention is drawn to the possibility. Prof. Bruck said that strong solutions of sublimate of mercury are often administered to the nose and the oral cavity without causing any damage to the patient. Prof. Joachimoglu pointed out that the diagnosis of poisoning should be made not on the basis of clinical symptoms, but only after chemical examination.

### *Qualification Statistics.*

In Germany the number of medical men has risen from 36,000 in 1921 to 42,000 in 1925. The number of qualifications, which was 1447 in 1913, rose in 1914 to the record number of 3882, because at the beginning of the war all the students who joined the army were entitled to be examined before they had quite finished their curriculum. In 1915 only 1116 qualifications were granted and in 1916 only 576, this being the smallest number on record for many years. In 1917 and in 1918 only 611 qualifications were granted as the universities were partly closed owing to the revolutionary troubles of the latter year. In 1919 the number of qualifications was still small for the same reason, being only 1319, but in 1920 it rose again to 3836, being nearly the same number as that of 1914. In that year the students who had returned from the war qualified in great numbers. Since that time the differences are less marked: in 1921, 2134; in 1922, 2336; in 1923, 2866; and in 1924, 2620 students qualified. The number is now about twice as great as that of two normal years before the war, producing an overcrowding which is further enhanced by the fact that only 600 to 700 medical men die every year. The profession is very unequally distributed throughout the country. In 1914 there were 9·6 medical men for each 100,000 inhabitants of big towns with a population above 100,000, and 3·8 for the remainder; in 1924 corresponding figures were 10·5 medical men for each 100,000 in big towns and 4·5 in the remainder; in 1925, 11·2 and 4·5 respectively; the increase of doctors has thus concerned only the big towns. In 1925 there was one medical man for each 900 inhabitants of big towns, one for each 1000 in towns with 20,000 to 100,000 inhabitants, and one for each 2500 in the small towns and the country. The average number throughout the country is one medical man for each 1500 inhabitants.

### *Unqualified Practice in Germany.*

The Medical Department has published statistics on the number of unqualified persons engaged in medical practice. Their number could be ascertained with accuracy, as according to law they must be registered by the authorities for reasons of control and taxation. Their number rose from 5063 in 1923 to 5648 in 1924, being an increase of 11 per cent. Their clientèle is largely composed of members of educated classes and they are consulted often for financial reasons, as they are believed to charge less than a qualified medical practitioner. Also the predilection for mysticism prevailing since the war, together with frequent advertising (not allowed to the medical profession), has aided to make unqualified practice popular. The report stated that 300 unqualified people were prosecuted, of whom 200 were punished; 47 prosecutions concerned the prescribing of drugs reserved to the medical profession; 43 were for artificial abortion; 33 for practice without fixed residence; 36 for offences against registration regulations; 27 for using a title similar to that used by qualified medical men; 24 for causing injury by neglect; 8 for causing death by neglect; 19 for indecent advertisements; 7 for unfair competition; 6 for libels on medical men; 3 for offences against public morals. The complaints were mostly lodged on behalf of the Society for Combating Unqualified Practice.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

### *Visit of English and American Medical Men to Vienna.*

A FEW days ago a large number of English ot rhino-laryngologists visited the clinics of the Vienn University and thus renewed time-honoured relatio which had been severed since 1914. The visitor at any rate if we may judge by the tone of the after-dinner speeches, appeared to be impressed wit the high standard of the work shown them. Th week another large body of English-speaking docto is in our midst. They are American medical me some 250 in number, who have come here on the trip through the European centres of learning. Th visit should have a lasting effect on the relatio between the U.S.A. and Austria, for it is intended t organise a regular exchange of teachers in medic schools and also of health officers between th countries. In his introductory speech the Preside of the American Medical Association of Vienn pointed out that Vienna is regarded in the Stat as the leading centre for studies of nose, throat an ear diseases and for surgery, but that pathologic anatomy, as it is taught and studied in Vienn should have even more importance in the eyes medical students from across the ocean. A speci series of lectures, embodying the latest researches an achievements in each branch of medicine, was hel in honour of the visitors. Prof. Wenckebach discusse the diagnosis of heart diseases, Prof. Eiselsber demonstrated brain surgery, Prof. Fuchs delivere a lecture on errors in ophthalmology, which we specially appreciated, and in Hajek's throat and nos clinic and in Neumann's ear clinic numerous cases cancer of the respiratory organs, labyrinthic case and other most interesting patients were demonstrate Dr. Wagner von Jauregg explained his method treating general paralysis of the insane with malari and showed cases apparently cured by these mean Moreover, the sanitary arrangements of the city, it water-supply, drainage system, hospitals, and th modern housing methods adopted by the municipalit were shown and explained. Especially the latt point is well worth careful attention. Vienna is th only city on the continent where the housin problem—one of the most burning problems sinc the war—has been attacked and nearly solved o a grand scale. By a specially adopted system taxation of the existing flats, houses, or dwelling the municipality has obtained means to erect a whol series of enormous buildings and blocks. providin healthy, modern, airy, and well-lighted dwellings f 25,000 families within two years. These houses, re people's palaces, are planned carefully in such a wa that every dwelling, every room has direct ligh ample bathing facilities have been provided, and als playgrounds for the children. A remarkable featu is the absence of dogs in these buildings. They ar banned for hygienic reasons. The foreign medic men were greatly impressed by this effort in th direction of preventive medicine—the housing develop ment cannot be better termed—which will, it hoped, help to make Vienna one of the healthies cities in Europe.

### *Generalised Infections caused by Ophthalmic Diseases.*

An interesting paper on general infections from a ophthalmic source was presented by Dr. Herren schwand to the Medical Society of Innsbruck recentl He stated that it is not always easy to prove th primary infection in the eye, as this may have bee of a transient nature. But pathogenic germs ca easily be shown to pass the naso-lacrymal ducts an thus enter the nose, the pharynx, the lung Especially the pneumococcus may be found, causin an acute coryza, or swelling of the deep cervica glands, or even articular inflammations. Maxe

Cowper and Enright have shown this with the *Bacillus prodigiosus;* the conjunctival infection brought the germs into the respiratory tract, oral infection into the intestinal tract. Purulent conjunctivitis due to the gonococcus may cause metastatic disease of the joints both in the adult and in the infant; a case of meningitis has been reported by Schall to follow it, and pyæmia with gonococcal abscesses has been repeatedly noted as a sequela. That a general infection can arise from tuberculosis of the eye has not yet been definitely proved although experimentally it is possible to infect internal organs of the animals used by introducing tuberculous matter into the conjunctival sac. The *Bacillus pseudo-tuberculosis rodentium* has been observed to cause disease of the glands in the neck, the primary lesion in the eye having escaped notice. Syphilitic primary infections of the eyelids, or conjunctiva, infections with anthrax or tetanus do not differ in any respect from those in other parts of the body. A severe encephalitis may be produced in an animal by inoculation of the virus of herpes into the cornea. It is remarkable that infection of the interior of the eyeball rarely causes a generalised infection; mostly the route is via the lacrymal duct, nose, and tonsils from the conjunctiva or cornea only.

### *First-aid Association of Vienna.*

At a recent function on behalf of the public ambulances, the ex-President of the Vienna police and former Prime Minister of Austria, Herr Schober, delivered an interesting report on the activity of the "Wiener freiwillige Rettungsgesellschaft" (Voluntary First-aid Association). This corporation was founded in 1881, after a fearful disaster, when nearly 1000 lives were lost in a fire at the municipal theatre, most of which could have been saved if a first-aid organisation had then existed. This association became a model for all similar bodies on the continent, and in the 45 years of its existence it has had ample opportunity to render assistance beyond the city of Vienna and even outside Austria, for example, after the earthquake at Messina. Altogether 561,253 persons have received medical or surgical assistance in cases of accident or sudden illness in the street. The record was reached in the year 1913, when 22,586 individuals were registered, whilst in 1925 this figure was also nearly reached, 22,438 persons having been taken care of, or an average of 62 per day. The society has two different accident departments in the city, so that cars with first-aid outfit and medical attendants can be called from the place nearest to the scene of disaster. A medical staff of 18 doctors and medical students, eight motor-ambulances, and adequate equipment for sending out, in case of need, 24 conveyances fitted with stretchers, surgical appliances, and other necessities, including complete gas- and smoke-proof outfits, belong to the regular outfit of the association. Its financial position has, however, become very serious, since the sum required for 1926 amounts to £15,000. Propaganda on a large scale has been organised to obtain the necessary funds. The medical work done by the members of the association is not negligible. Regular first-aid classes are held every two months, open to all adults, with practical classes at the end. Members of the police force, school-teachers, factory inspectors, and sportsmen have made arrangements for special classes, and the beneficial effect of the spread of first-aid knowledge cannot be over-estimated.

### *Congress of the German Society for Urology.*

The seventh convention of the German Society for Urology will take place in Vienna from Sept. 30th till Oct. 3rd, with Prof. Blum presiding. The proceedings have been divided into three large groups—viz., (1) pain in urology and its prevention; (2) pathology, pharmacology, and therapy of anuria; (3) malignant disease of the bladder, its pathology and treatment. To introduce each of these three topics three men have been chosen, amongst them scientists from Austria, Germany, Hungary, United States of America, Japan. They will present their theses conjointly in the mornings and the discussion will take place in the afternoons. At the same time the Hungarian Urologic Society has invited all the members of the German Society to pay a visit to Budapest after the proceedings on Sunday, Oct. 3rd, and to inspect the special hospital in that city.

# Public Health Services.

## SCHOOL MEDICAL SERVICE.

IN the following table the figures given in the reports from Hull, Scarborough, and Margate are set out:—

| Name of town. | No. on roll. | Av. elem. school attendance. | No. of routine children examined. | No. of special examinations and re-inspections. | Percentage of children found on routine examination requiring treatment.* |
|---|---|---|---|---|---|
| Hull .. | —† | —† | 16,841 | 13,276 | 9·8 |
| Scarborough | —† | —† | 1,210 | 1,067 | 20·51 |
| Margate .. | 3,308 | 2,887 | 1,097 | 831 | 0·8 |

* Excluding uncleanliness and dental defects. † Not given.

### *Margate.*

The small number of children in the elementary schools must come as a surprise to those who have seen Margate only in the summer-time. Dr. Rowan McCombe's report illustrates how a small population like this affects the organisation. On the one hand, the M.O.H. is himself not only the S.M.O. and anæsthetist to the clinic, but also physician to the Welfare Centre, thus ensuring close coördination, but entailing much work. On the other hand, with such small numbers there is naturally less likelihood of the town possessing any kind of special school. To fill the need joint action is necessary. Dr. McCombe states that a home for the mentally defective is badly needed in Kent. It would seem that accommodation for those suffering from some physical defects is equally needed. The number of exceptional children reported seems rather low—e.g., four mentally defective and two epileptic out of some 3000 children. The number of heart cases is, as Dr. McCombe says, surprisingly few, only one case of organic disease being found in over 1000 children. That the interest and confidence of the parents has been won is shown by the fact that 80 per cent. of the parents attend the medical inspections. Sixty-nine cases of tonsils and adenoids were operated on at the excellent clinic out of 73 who were recommended for operation, and of 176 children with errors of refraction 171 got glasses. The dental scheme is now so extensive that every child at school can have his teeth completely treated every other year; 1127 cases were dealt with this year, more than a third of the children in the schools.

### *Scarborough.*

Dr. S. F. Linton, M.O.H. and S.M.O., writes a brief introduction to the report by his assistant, Dr. Anne Roxburgh, which shows that much attention is given to the infants. A nursery school and a special nursery class are held. The school clinic is also the Infants Welfare Centre; both are run by the S.M.O., and so a continuous record is kept of all children who attend. The careful return of exceptional children shows that while the present accommodation is not adequate a fair effort is now being made to meet the need. A special class, not yet recognised under paragraph 5 of the Education Act, 1921, is held for mentally defective child.

The opening of the new orthopædic hospital at Kirkbymoorside will greatly help in the treatment of crippled children. There are some 65 delicate children, four of whom attend a special voluntary class. There is no open-air school, though even in this healthy town such a school would have much economic value. Facilities for treatment appear to be satisfactory, and 80 per cent. of those requiring dental treatment obtained it. Dr. Roxburgh recommends operation for tonsils and adenoids (1) if the tonsils interfere with speech or respiration; (2) where there are recurrent attacks of tonsillitis; (3) where there are enlarged cervical glands; (4) where there is associated ear trouble. These classes are obviously not meant to be exhaustive, and Dr. Roxburgh is no doubt acquainted with recent researches claiming relative immunity from infections for children who have had their tonsils removed. In the sanitary survey of the schools neither the accommodation nor the date of erection is given, and trough closets which are becoming less favoured in modern schools were found in six of the seven schools in the town.

### *Hull.*

Dr. J. W. Fraser presents his last report, and all who know his work in Hull will regret his coming retirement. The prompt remedy of defects at the youngest ages largely accounts for the comparatively small number of defects found; 87·3 per cent. of those needing dental treatment received it. The condition of the teeth of the entrants is apparently very bad, but with an increased dental staff it will be found possible to deal with children at an earlier age, perhaps before school life starts, as is done in Cambridge. Cleanliness shows continual improvement and is 20 per cent. better than last year. An orthopædic scheme has now been sanctioned, and includes the establishment of a special clinic and the appointment of an orthopædic specialist. Under this scheme the present excellent physical defective school will ultimately take children between the ages of 2 and 16 years suffering from non-tuberculous crippling, the tuberculous cases being dealt with elsewhere. Already the age of admission has been reduced from 7 to 5 years. It is to be regretted that owing to the present financial restrictions it is impossible to start an open-air school. The Charity Organisation Society included Hull in their inquiry as to the adequacy of the accommodation for epileptics in this county. In Hull there are 61 cases of epileptic children, of whom only 12 are considered severe; of these eight only were deemed to be educable. This is in keeping with the society's conclusion that although there is a shortage of accommodation in the country as a whole yet in most areas the numbers are too small to warrant local institutions, and the difficulty must be met by the provision of special residential schools under several joint authorities. Dr. Fraser has always taken an especial interest in the backward and mentally defective. For the backward, which class probably includes the severely dull and some of the stable high-grade defectives, he has craft classes which have been further extended. For mental defectives he has a very efficient special school. He gives the after-history of the pupils of this school in regard to employability, and these figures are also given for the deaf. Omitting those who cannot be traced or are dead, among the mentally defectives 62 out of 183 are in work (34 per cent.), and among the deaf 31 out of 36 (86 per cent.). The figure for the deaf is considerably above that found elsewhere, but the results of the mentally defectives seem not so good. It might perhaps be higher if all the children were kept till 16, and given more advanced manual training. It is true that often it is easier to find employment for a child of 14, but usually only of a temporary nature. It may also be that a few high-grade defectives who would do well never reach this special school, but remain in the craft classes or even in the elementary schools. In conclusion, Dr. Fraser thanks all those who have worked with him—gratitude which is likely to be mutual.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 12TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week:—Small-pox, 201 (last week 210); scarlet fever, 1370; diphtheria, 796; enteric fever, 34; pneumonia, 709; puerperal fever, 55; cerebrospinal fever, 9; acute poliomyelitis, 8; acute polioencephalitis, 2; encephalitis lethargica, 44; dysentery, 10; ophthalmia neonatorum, 103. There were no cases of cholera, plague, or typhus fever notified during the week.

*Deaths.*—In the aggregate of great towns, including London, there were 2 (0) deaths from enteric fever, 29 (2) from measles, 4 (2) from scarlet fever, 36 (3) from whooping-cough, 22 (7) from diphtheria, 41 (10) from diarrhœa and enteritis under two years of age, and 67 (5) from influenza. The figures in parentheses are those for London itself.

# The Services.

### ROYAL ARMY MEDICAL CORPS.

Lt.-Col. W. A. Woodside retires on retd. pay.

Lt. J. F. P. Gallagher to be Temp. Capt. and temporarily relinquishes the rank of Lt.

#### TERRITORIAL ARMY.

Lt.-Col. D. C. L. Orton to be Bt. Col.

2nd Lt. J. G. Graham (late R.F.A., Special Res.) to be Lt.

2nd Lt. E. R. C. Walker (late Royal Highlanders) to be Lt.

E. A. L. Murphy to be Lt.

### INDIAN MEDICAL SERVICE.

Lt.-Col. A. B. Fry to be Col.

Temp. Lts. Jagan Nath Madan and Hans Raj Balooja to be Temp. Capts.

The King has approved the retirement of Lt.-Col. G. McPherson.

Bubonic Plague in South Africa.—The Bulletin of the Department of Public Health, Pretoria, for the week ended May 22nd, gives the following reports respecting bubonic plague in the Union:—Middelburg District (Cape): The third European bubonic case, reported in last week's Bulletin, at Sakfontein, has died. Two further cases, one European and one coloured, are reported from the same farm. The disease in these two cases is of the pneumonic type. Hoopstad District (Orange Free State): Two further native fatal cases are reported at Protestpan, 15 miles from Bullfontein.

Memorial to the late Dr. Alfred Miller.—On the afternoon of June 6th, in the little chapel of the County Mental Hospital, Hatton, Warwickshire, a new altar and reredos were dedicated by the Bishop of Coventry in memory of Dr. Alfred Miller. A mural tablet bears the following inscription: "To the Glory of God the Chancel of this Chapel was renovated and the new Altar and Reredos erected by his friends and fellow workers in memory of Dr. Alfred Miller, Medical Superintendent of this Hospital from May 9th, 1889, to the day of his death, December 4th, 1923."

Livingstone College, London.—Commemoration Day was celebrated on June 9th, when the Bishop of Chelmsford presided over a large number of guests. The Bishop said that the College exists to help all missionary societies of the church and churches in order that missionaries might have some kind of knowledge as to the management of their own health and that of other people. The Rev. B. T. Butcher, of the London Missionary Society, Papua, gave an address, and Mr. R. L. Barclay, hon. treasurer of the College, said that in memory of Dr. C. F. Harford a fund had been established. They had aimed to raise £3000 and to date had received £770. The Principal, Dr. T. Jays, said that missionary societies should see to it that the men they sent out should know how to preserve their own health. He had had letters during the past few weeks from many old students expressing gratitude for the knowledge gained at Livingstone College. Last year 103 students entered the College.

"Audi alteram partem."

## VENEREAL DISEASE LEGISLATION.

*To the Editor of* THE LANCET.

SIR,—Adverting to the very interesting leading article on this subject in THE LANCET of June 19th, it will interest you to note that proposals of a somewhat similar kind had been made by me in 1918 and again in 1922. The proposals impose certain obligations upon infected persons in regard to obtaining medical advice, and also in regard to knowingly or wilfully infecting any other person with venereal disease. The other points of equal importance, as you will note, are alluded to in the other clauses. The object of bringing these proposals forward was to afford an opportunity for their discussion. Unfortunately, however, opposition from bodies, professedly interested but not fully conversant with the facts, prevented this course being followed.

I am, Sir, yours faithfully,
E. W. HOPE.

Liverpool, June 19th, 1926.

*** Prof. Hope's proposals at the later of the two dates he mentions took the following form:—

Public Health Department, Liverpool, March 10th, 1922.

*Venereal Diseases: Suggested Regulations.*

*Duty of Person Infected.*—(1) Every person suffering from any form of venereal disease as soon as he is aware or has reason to believe that he is suffering from such disease, shall forthwith consult a medical adviser with respect thereto, and shall furnish to him his correct name and address and place himself under his treatment. (2) Every such person shall continue to attend or be attended by his medical adviser, and to follow his advice and treatment until he is deemed free from infection. (Provision to be made for change of medical advisor and for routine procedure in case of neglect to continue treatment.) (3) No person shall knowingly or wilfully infect any other person with venereal disease or do or permit any act likely to lead to such infection.

*Duty of Parent or Guardian.*—Every parent, guardian or person in charge of child (under 16 years of age) or mental defective suffering from any form of venereal disease, and who knows that such child or defective is suffering from such disease, shall cause the child or defective to be treated and continue treatment for such disease by a medical adviser.

*Penalties.*—Section 1 (3) of the Public Health Act, 1896, provides that if any person wilfully neglects or refuses to obey the execution of any regulation under Section 130 of the Public Health Act, 1875, he shall be liable to a penalty not exceeding £100 and in the case of continuing the offence of a further penalty of £50 per day.

*Duties of Medical Practitioner.*—(1) The doctor shall direct the patient's attention to the infectious character of the disease, and to the necessity of continuing treatment until free from liability to infect, and to the penalties prescribed. (2) To arrange for transfer to another medical adviser when the patient so desires. (3) When a patient discontinues medical treatment without adequate reason, the medical adviser will forward his name and address to the medical officer of health. In any case where a fee is not paid by the patient to the doctor, the provision for such payment shall be made on the lines which the Ministry have already authorised in Liverpool in regard to the domiciliary treatment of non-insured tuberculous persons Suitable forms shall be provided for the use of medical practitioners intimating the obligations upon patients—arrangements for transfer when necessary—and forms of notice to the medical officer of health as to acceptance of a patient by the practitioner, and when necessary, his non-attendance. Drugs specially necessary for treatment shall be provided free of charge to medical men as hitherto. Ordinary prescriptions shall be paid for as in the scheme for domiciliary treatment of tuberculosis.

*Duty of Medical Officer of Health.*—The medical officer of health, on receipt of a notice from the medical adviser in regard to any patient, shall make inquiries from the person named as to the reason for discontinuance of treatment, and unless satisfied shall cause an information to be laid in a court of summary jurisdiction.

*To the Editor of* THE LANCET.

SIR,—The leading article under the above heading in your issue of June 19th did not refer to the Bill to amend the Venereal Disease (1917) Act introduced by Mr. Basil Peto in the House of Commons on June 16th. The object of this Bill is to amend the Venereal Disease Act (1917), *so as to give effect to* the recommendation contained in Clause 14 of the report issued in 1923 of the Committee of Inquiry on Venereal Disease presided over by Lord Trevethin. Under the Venereal Disease Act (1917), the extraordinary position arises, which was clearly unintended and which has arisen owing to some error in drafting, whereby a chemist may sell any so-called disinfectant for the prevention of venereal disease, the public having no guarantee that such so-called disinfectants are in fact efficient disinfectants. The chemist may also supply oral instructions for the use of such disinfectants, but he may not supply printed or written instructions drawn up by any authoritative person or persons. Mr. Peto's Bill appears to contain only the amendments which are absolutely necessary—and which have been previously advocated by the British Social Hygiene Council and the Society for the Prevention of Venereal Disease—in a simple and practical form. I venture to hope that you will be able to exert your powerful influence on behalf of a second reading without opposition.

I am, Sir, yours faithfully,
H. WANSEY BAYLY,
Hon. Secretary, Society for the Prevention of Venereal Disease.

Harley-street, W., June 21st, 1926.

*** Our Lobby Correspondent reports Mr. Peto's speech on p. 1281.—ED. L.

## VOLUNTARY TREATMENT IN MENTAL HOSPITALS.

*To the Editor of* THE LANCET.

SIR,—I desire to bring an important medical issue, affecting the community, to the notice of the medical profession in Scotland. In itself mental illness is always distressing, but it is made much more so if, before treatment can be obtained, a patient must be certified by doctors and registered by the sheriff as a "*person of unsound mind.*" This additional suffering is, however, in most cases quite unnecessary. It is, for example, not inflicted on the majority of patients of the richer classes, for these regularly enter our mental hospitals not as certified but as voluntary patients. Their admission as such enables them also to avoid the slur that unhappily attaches to those who have been treated in mental hospitals, as in the eyes of the law a voluntary patient, whatever his mental condition may be, is not regarded as a "person of unsound mind." To many it may come as a revelation that two-thirds and more of those with means, who undergo treatment in our mental hospitals, do so as voluntary patients.

The poor are entitled to exactly the same privileges as those with means, but owing to ignorance and misunderstanding their rights have not been brought to their notice, and in consequence over 90 per cent. of rate-supported patients are certified and registered as "*persons of unsound mind.*" Not 1 per cent. receives treatment as voluntary patients. There is something amiss when such a difference exists in the means of obtaining treatment for an illness by members of these two classes. Among the misunderstandings is the belief that a voluntary patient costs the ratepayers more than a certified patient. In the latter case it is said the Government gives a grant-in-aid amounting to £7 0s. 6d. per annum, whereas no such relief is afforded the ratepayer in the case of a voluntary patient. This is an error. The cost to the ratepayers is exactly the same in both cases, as the Government grant is not calculated on a capitation basis but consists of a fixed sum given annually as a grant-in-aid to the parishes, irrespective of the number of patients or whether they be certified or voluntary.

Another impression commonly held is that no person of unsound mind whom it is possible to certify can be admitted as a voluntary patient. This also is an error. It has been stated by the highest legal authority on matters connected with lunacy, and his views have not been opposed officially, that if *such a condition ever existed it was repealed* in the Act of 1913. There is one condition, and one only, to be observed, and it is that the patient should desire to submit to treatment.

The procedure is simplicity itself. The patient gives to the medical superintendent the following letter: "Dear Sir,—I desire to be admitted as a voluntary patient to the (name the mental hospital). I am, &c." In other words, a patient entering a mental hospital voluntarily has to express his wish in writing. He has also to give three days' notice of his intention to leave. A rate-supported patient desiring this form of treatment must have the approval of the officials of the parish council—namely, the medical officer and the inspector. I would appeal to every doctor in Scotland to make this provision known to the poor and to recommend every patient of his requiring treatment in a mental hospital to enter as a voluntary patient.

Only those who have seen the distress that medical certificates and sheriffs' orders occasion to patients and to their relatives and know how unnecessary they are in the majority of cases, can realise all the good that will result from following the above advice. The sick in mind and the poor will benefit, and mental hospitals will, we hope, be regarded, not as places of detention, but as hospitals for medical treatment like other hospitals. As for doctors they will be relieved of a distasteful, a thankless, and a perilous public service.—I am, Sir, yours faithfully,

GEORGE M. ROBERTSON.

University of Edinburgh, June 21st, 1926.

## BEAT-KNEE AS A FORM OF RHEUMATISM.

*To the Editor of* THE LANCET.

SIR,—In the following list of ten beat-knee cases which have come before me consecutively, I have been impressed by two factors at least common to most of them—namely, inflamed gums and a partiality for acids such as vinegar and sauces, whilst the majority have a liking for meat. Nail-biting is a very common habit amongst these men and several suffer from pharyngeal catarrh. Lumbago is, or has been, present in several, whilst the heart in several cases was not normal.

A, aged 18. Has slight swelling over the knee; eyes and pharynx inflamed; bites nails; cannot play football because he is short-winded; gums inflamed. Heart not normal. Very fond of meat and salt.

B, aged 49. Had beat-knee of left leg May, 1925, and of right leg eight years previously; three months ago had lumbago. Is very fond of vinegar and meat. Gums inflamed. Takes no milk.

C, aged 57. Has had rheumatism, and the heart is not normal; gums inflamed. Very fond of pickles.

D, aged 28. Had beat-knee in 1925. Complains now of "strained back." Has a "cold"; pharynx inflamed; bites nails. Heart not normal. Smokes heavily. Very fond of vinegar.

E, aged 43. Has pyorrhœa. Heart not normal. Very fond of meat. Pale.

F, aged 37. Is subject to "indigestion"; tongue very furrowed; heart not normal; short of breath; gums inflamed; bites nails.

G, aged 27. Bites nails; gums inflamed. Very fond of sauce.

H, aged 23. Very fond of vinegar and dislikes milk. Heart not normal; pyorrhœa; throat inflamed; bites nails.

I, aged 36. Had beat-knee six years ago on the other leg; gums inflamed. Fond of vinegar and dislikes milk. Throat inflamed.

K, aged 19. Gums and throat inflamed; heart not normal. Very fond of vinegar. Bites nails.

Cases B and D are interesting as showing a sequence of beat-knee and lumbago, for compensation purposes called "strained back." Cases B and I show the knees affected alternately. There is no doubt that beat-knee, like rheumatism, is the expression locally of a constitutional disturbance and most observers will agree that the disturbance is identical. Carditis in children, as far as my experience goes, occurs only in those who dislike milk, but are fond of acids like vinegar. Nearly all these children have inflamed or puffy gums and many bite their nails.

As chilblains occur in the extremities of those persons who have a certain predisposition, by a local interference with the capillary circulation, so beat-knee occurs in a person with the rheumatic predisposition by a local irritation of the capillary circulation over or in the region of the bursa patella. Did friction alone give rise to beat-knee the majority of colliers would suffer from this trouble; as it is, the percentage is not higher than that of heart disease amongst the same class and depends, like the latter disease, on the presence of the necessary predisposition.

I am, Sir, yours faithfully,

G. ARBOUR STEPHENS, M.D.,

Consulting Cardiologist, King Edward VII. Welsh
June 21st, 1926. National Memorial Association.

## THE TITLE OF APOTHECARY.

*To the Editor of* THE LANCET.

SIR,—In your editorial remarks anent a letter on this subject in your issue of June 19th you very rightly draw attention to the dissociation between the appellation of apothecary and that of general practitioner.

The Society of Apothecaries grants a licence to practise medicine, surgery, and midwifery in the same way that the Royal College of Physicians grants its licence, but the holders of the former are no more apothecaries than the latter are physicians. To become an apothecary it is necessary to be a freeman of the Society which is one of the City Guilds, to become a physician entails being a Member or Fellow of that College.

By a recent regulation any newly qualified licentiate of the Society of Apothecaries can become a freeman by complying with the requirements and paying a modified fine by instalments. The Society of Apothecaries is almost the only one of the City Guilds which still actively pursues the objects of its charter granted by James I. (although it no longer manufactures drugs), but being on this account largely composed of men in the medical profession, it is not necessarily confined to such, any more than, as you remark, are the freemen of the Cordwainers Company composed of merchants in the leather of Cordova.

I am, Sir, yours faithfully,

T. VINCENT DICKINSON, M.D.,

June 21st, 1926. Master of the Society of Apothecaries.

## THE DANGER OF OPIUM IN COMBINATION WITH OTHER DRUGS.

*To the Editor of* THE LANCET.

SIR,—Happening to pick up an old number of THE LANCET, I came across a paragraph on aspirin tablets with Dover's powder. May I say that in my experience Dover's powder should not be compounded with aspirin? In most cases it acts well, but in some cases susceptible to opium it retards the action of aspirin as regards secretion and causes serious danger. Caffeine gr. i. (instead of the Dover's powder) and followed by hot toddy is far safer and better in *pneumonia, influenza*, &c. Small doses of morphia act capriciously, and morphia should always be given in a single dose, and for a definite purpose. I have seen iodism from gr. ii. of potassium iodide when combined with tr. camph. co. in small doses. If a sudorific does not set up free perspiration it becomes dangerous, the most striking example perhaps being the hyperpyrexia of acute rheumatism from sodæ salicylate retention, when perspiration stops.

In my view, morphia should always be used *alone*.

I am, Sir, yours faithfully,

Newcastle-upon-Tyne, June 19th. T. M. ALLISON.

## RADIOLOGICAL INVESTIGATION ON THE ACTION OF PURGATIVES

*To the Editor of* THE LANCET.

SIR,—In the annotation in your issue of June 19th on the recent radiological investigations on the action of purgatives carried out by Prof. P. Alessandrini, of Rome, it is stated that such investigations had hitherto only been made on animals. It is, however, 18 years since Mr F. Cook and Mr. E G. Slesinger, then students and now assistant obstetric surgeon and assistant surgeon respectively at Guy's, carried out a series of radiological and other observations on the action of saline aperients with me. Our results were communicated to the Therapeutical Section of the Royal Society of Medicine and were summarised, together with subsequent radiological investigations of my own on the action of aloes, cascara, castor oil, and calomel, in the first edition of my book on Constipation published in 1909. In 1910 Stierlin made similar observations with senna, and in 1914 Dr. W. R. Reynell, who was at that time my house physician, investigated the action of liquid paraffin It is impossible to give more than a very short summary of our results in a letter, but on the whole they agree very closely with those of Prof. Alessandrini

We found that saline aperients act only on the colon As they frequently act within an hour—i e long before they have reached the large intestine, both according to Alessandrini's and our observations—it is clear that they cannot act, as is still commonly taught, by attracting fluid into the lumen of the bowel Moreover, the liquid stools contain no excess of the salt, which is chiefly excreted in the solid stool passed the next day We believed that they must, therefore, act only after absorption, but in view of the reflex contraction of the gall-bladder, which Meltzer has shown occurs when magnesium sulphate is introduced into the duodenum, it is possible that the true explanation is that the salts also give rise to a duodeno-colic reflex, which evacuates the fluid contents of the proximal colon. My observations showed that cascara acts on the small as well as the large intestine, and not only on the latter as stated by Alessandrini On the other hand, aloes and senna act only on the colon. Castor oil acts on the small intestine as well as the colon; the delay it causes in the evacuation of the stomach is due to the inhibitory action it shares with all fats, as Pavlov showed many years ago Lastly, liquid paraffin only accelerates the transit through the colon.

I entirely agree with your annotator that observations of this kind show that radiological methods are valuable in the study of the complex questions of experimental pharmacology, but it seems a pity that in reviewing Italian work published in 1925 he should have ignored the investigations on the subject done more than ten years earlier in England.

I am, Sir, yours faithfully,
ARTHUR F HURST.

New Lodge Clinic, Windsor Forest June 21st, 1926

---

UNIVERSITY OF LONDON CLUB —A well-attended reception was held at the club on Tuesday evening, June 22nd, to meet Prof Ernest Gardner, Vice-Chancellor of the University, Mr S. L. Loney, chairman of Convocation, and members of the Senate, and there was a distinguished gathering of graduates in many faculties. The chairman of the club, Mr Walter Seton, D Lit in welcoming the guests, referred to the recent introduction of a widened basis of membership in the club Hitherto membership has been limited to graduates, teachers, and officers of the University of London and others connected with the University and its colleges, schools, institutions, and organisations. It has now been decided to admit to membership graduates of other universities, persons who, though not graduates of the University, hold one of the diplomas granted by the University, and others who have taken an approved professional qualification such as the M R C.S., L.R C.P. He expressed the hope that the existing membership of 700 would soon be raised to 1000, which could be done without overcrowding the present accommodation An admirable programme of music was provided in the club hall by the University of London Musical Society

## NOTES ON CURRENT TOPICS

### *Venereal Disease Act (1917) Amendment Bill.*

MR BASIL PETO presented a Bill to permit the sale by chemists of disinfectants for protection against venereal disease. The Bill was read a first time.

The object of the Bill which I am asking leave to introduce, said Mr Peto, is to give effect to the recommendation of the Committee, appointed by the Ministry of Health, which sat under the chairmanship of Lord Trevethin, contained in Clause 14 of their report issued in 1923, and which is as follows:—

> "We think that the law should be altered so as to permit properly qualified chemists to sell ad hoc disinfectants provided such disinfectants are sold in a form approved and with instructions for use approved by some competent authority"

Clause 1 of the Bill amends Clause 2 of the Venereal Disease Act, 1917, so far as that Act relates to the prevention of disease, and Clause 2 of the Bill provides for the setting up of the competent authority As to the present state of the law I cannot do better than quote what the Minister of Health said in reply to a deputation which waited upon him in July, 1923, and which was introduced by the late President of the Society for the Prevention of Venereal Disease (Lord Willoughby de Broke) The Minister said:—

> 'I have been to the best fountain I could, the Law Offices of the Crown, and I have put to them certain questions as to the exact meaning of the relevant section to the Act of 1917 We have this position, that to-day a chemist may sell ad hoc disinfectants for the purpose of prevention. To-day a chemist may verbally recommend to a customer such preparations for such purposes What he may not do is to give any written or printed instructions, although he may give verbally such instructions to the customer . It is clear that it would require an alteration in the law to permit the chemist to give printed or written instructions, and personally I think that if these things are to be sold, printed or written instructions should be supplied with them. It would also be necessary to pass legislation if the sale of these preparations is to be limited to such as are approved by a competent authority"

There is agreement as to the desirability of taking all steps possible for the prevention of this terrible disease The trouble so far has been as to what should be the competent authority A great deal of evidence as to the efficacy of preventive measures accumulated during the late war, of which I have only time to give two examples. Sir James Barrett who was in medical charge of the Australian Forces during the war, says:—

> "In my experience primary prophylaxis has been practically certain in its results."

And he states that in one camp out of 4100 men who reported exposure to infection that as a result of primary prophylaxis only 13 infections resulted Surgeon Captain Hamilton Boyden, who was in medical charge of the Naval Gunnery School at Portsmouth during the two years from 1918 to 1920, says that 923 bottles of 1 in 1000 solution of potassium permanganate were supplied to men who intended to incur danger of infection; and only one man was infected During 1917 the men at the Royal Artillery Barracks at Portsmouth were carefully instructed to disinfect without delay, and out of 3750 only five were infected during a period of nine months There is also evidence from Colonel Harrison as to what would be the effect of similar steps on the civil population. His experience during the war shows what could be done to reduce venereal disease in the civil community It seems to me perfectly clear that the civilian population should have free access to reliable preventives against venereal disease It is not only a question of the present generation, we have to consider the effect of this terrible scourge on future generations. The best medical opinion is unanimous that a very large proportion of the cases of paralysis, malformation, mental deficiency, insanity, epilepsy and blindness, which cost the country almost untold loss in the efficiency of the population, and a direct loss in keeping these unfortunate victims, are due directly to parental syphilis or gonorrhœa.

I will give the House, Mr. Peto continued, one example as to blindness The Report of the Departmental Committee on the Causes and Prevention of Blindness, which was issued by the Ministry of Health in 1922, states that of 1835 cases of school blindness occurring in the schools for the blind of the London Education Committee, in 1920 alone, 309 were due to parental gonorrhœa and 618 due to parental syphilis The cost of the present method of dealing with this disease exclusively by curing it, instead of dealing with it, as far as we can, before the germ is allowed to penetrate from the surface, is, according to the Annual Report of the Ministry of Health for 1924-25, very

The grants paid in one year in aid of venereal disease schemes amounted to £281,000, and the cost to local authorities of carrying out those schemes was over £358,000, making a total of £600,000. That is but a very small part of the cost to the country as a whole of the results of this terrible disease. I appeal to the House, not only to give the Bill a first reading, but, as all quarters of the House are agreed as to the need of the Bill, to give it a second reading in due course. Whatever else this House may do before the end of the session, at least we should pass this measure for the relief of suffering humanity.

The question being put, the Bill was ordered to be brought in by Mr. Basil Peto, Mr. Bennett, Major-General Sir John Davidson, Sir William Davison, Lieut.-Colonel Fremantle, Mr. Haden Guest, Lieut.-Commander Kenworthy, Dr. Drummond Shiels, Mr. Snell, and Dr. Watts.

### *Vaccination Bill.*

Clause 1 of the Vaccination Bill, introduced in the House of Commons on June 15th, by Mr. GROVES, states that no person shall be subjected to any penalty or loss or disability of any kind for refusing to be vaccinated or for refusing to cause any child or young person to be vaccinated. Clause 2 states that no payment in respect of vaccination shall be made out of any monies voted by Parliament or out of any local or general rate. Clause 3 repeals Sections 29 and 31 of the Vaccination Act, 1867, and Section 1 (3) of the Vaccination Act, 1898.

## HOUSE OF LORDS.

THURSDAY, JUNE 17TH.

### *Midwives and Maternity Homes Bill.*

THE Midwives and Maternity Homes Bill was read the third time and passed.

## HOUSE OF COMMONS.

WEDNESDAY, JUNE 16TH.

### *Medical Examination of British Seamen in New York.*

Colonel PERKINS asked the Secretary of State for Foreign Affairs the result of any representations made to the American authorities on the subject of the enforced medical examination of all British seamen sailing from these islands; and why any such treatment was necessary.

Sir CLEMENT KINLOCH-COOKE asked the Secretary of State for Foreign Affairs whether he was aware of a new regulation imposed by the New York port health authorities requiring the crews of British liners and other British seamen on arrival at New York to undergo medical examination by an American doctor before they were allowed to go on shore, and that such examination subjected the seamen to the necessity of undressing and other indignities; and whether he would take steps to approach the Government of the United States of America with a view to putting an end to a practice that was resented by British seamen.

Colonel DAY asked the Secretary of State for Foreign Affairs if his attention had been drawn to the fact that British seamen arriving at New York were being subjected to compulsory medical examination by the port medical officers; and, in view of the resentment expressed by the crew of the *Majestic*, would he cause representations to be made with a view to the withdrawal of this newly enforced regulation.

Sir HARRY BRITTAIN asked the Secretary of State for Foreign Affairs whether his attention had been called to the additional medical examination of sailors on British liners entering the port of New York; and whether, in view of the feeling which had been aroused on this matter, he could see his way to take up this subject with the authorities concerned.

Sir A. CHAMBERLAIN replied: The examination of the seamen took place under Section 105 (F) of the Immigration Laws and Regulations of 1925, which enables United States immigration officers to subject alien seamen to the same medical examination requirements as are imposed upon alien passengers. As at present advised, I do not consider that any useful purpose would be served by making representations to the United States Government.

Colonel DAY: Can the right hon. gentleman say whether the seamen of vessels flying other flags have been subjected to the same medical examination?—Sir A. CHAMBERLAIN: This is not a new law; but so far as I know the practice in this particular case is rather an exception to the usual practice.

Mr. B. SMITH: While it may not be a new law, it is certainly a new custom, and will the right hon. gentleman consider adopting measures in this country to retaliate against the action of the American authorities?—Sir A. CHAMBERLAIN: I would submit to the hon. gentleman that that suggestion is hardly conducive to the promotion of friendly relations between our two countries. I do not think that at the present time I can make any representations.

Dr. WATTS: Is the right hon. gentleman aware that the presence of small-pox in this country, and the fact that effective vaccination is a preventive against it, is one of the reasons for this examination to make sure that the men are properly vaccinated?—Sir A. CHAMBERLAIN: That may be true, but I am not aware of it.

Lieut.-Commander KENWORTHY: Will the right hon. gentleman represent to the United States authorities that it is repugnant to British ideas to examine seamen only, and not the officers of the ship?—Sir A. CHAMBERLAIN: I am not called upon to make any representations of that kind.

Mr. PALING: Is there any indication that this practice is likely to continue, or is it a solitary instance?—Sir A. CHAMBERLAIN: I think a succession of these questions would certainly ensure its continuance.

### *Training of Health Visitors.*

Mr. GRIFFITHS asked the Minister of Health the amount of money which had been paid by the Government in grants each year since 1919 towards the training of health visitors. —Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: The grants paid towards the training of health visitors since 1919 have been as follows: 1920–21, £2395; 1921–22, £1832; 1922–23, £1233; 1923–24, £1137; 1924–25, £890; and 1925–26, £567.

### *Foreign Pork and Public Health.*

Mr. WILLIAM THORNE asked the Minister of Health whether, seeing that under the Public Health (Meat) Regulations of 1908 it was decided to forbid the importation of what were known as box loins of pork from America, he would say when this ban was lifted; if he was aware that lately box loins of pork of a character similar to those banned in 1908 had been offered for sale in Smithfield; and what assurance could his department or the Smithfield inspectors give that the present imports were more fit for human consumption than those which were prohibited in 1908.—Mr. NEVILLE CHAMBERLAIN replied: The Public Health (Foreign Meat) Regulations of 1908 prohibited the importation of box loins of pork not bearing an official certificate of the country of origin which was declared by the Local Government Board to be admissible as evidence that the pork had been found by a competent authority to be free from disease, and otherwise to satisfy public health requirements. The official certificates of various countries have from time to time been declared to be admissible for this purpose. In the case of the United States of America the prescribed declaration of admissibility was published in the *London Gazette* on May 2nd, 1922. Before making this declaration, my predecessor satisfied himself that the certificate of the United States Government provided all the necessary guarantees for the safeguarding of the public health.

THURSDAY, JUNE 17TH.

### PUBLIC HEALTH IN SCOTLAND.

The House went into Committee of Supply on the Scottish Estimates, Captain FITZROY, Deputy Chairman of Committees, in the chair.

On a vote of £1,858,345 for the salaries and expenses of the Scottish Board of Health, including grants and other expenses in connexion with housing, grants to local authorities, grants in respect of benefits and expenses of administration under the National Health Insurance Acts, &c.,

Captain ELLIOT (Parliamentary Under-Secretary of Health for Scotland) said that the vital statistics for Scotland showed that the hope that had been expressed last year that the movement of the curves, which had been in an unfavourable direction in 1924, would not be maintained, that the lost ground would be recovered, and that they could look forward to a continuance of the improvement in the general vital statistics of the country which had been a feature of the last 50 years, and certainly an increasing feature of the past few years, had been realised. The general death-rate, which in 1924 was 14·4, had fallen to 13·4; and the infantile mortality, which in 1924 was 97 per 1000, had gone down to 90. The death-rate between one and five years had gone down from 15 to 12, and was equal to the rate for 1923, which was the lowest ever recorded in Scotland. Infantile mortality in its turn was less than for any previous year except 1921 and 1923, so that in the case of small children they had a mortality as low as they had ever registered before, and there were only two years in which it had been lower in the whole history of the country. A continuous fall such as they had seen in the mortality statistics of infants, children, and adults showed clearly that the general physical condition of the people was being maintained in spite of a long continued depression without parallel in the history of the country. That was reflected also in the tuberculosis rate, which had fallen from 80 per 100,000 in 1924 to 76, while in non-pulmonary cases it had gone down from 36 to 34. In both these cases the death-rate last year was the lowest that had ever been recorded in Scottish vital statistics. In the case of pulmonary tuberculosis the death-rate was not only the lowest ever recorded for Scotland, but it was a record for the whole of Great Britain. It was better than any other part of the United Kingdom. The English rate was 83 and the Scottish rate was 76, which seemed to show that the campaign that had been embarked upon was definitely beginning to bear fruit. They were not so fortunately placed with regard to non-pulmonary tuberculosis, but it might be that the various campaigns for cleaner milk and better food generally would have some effect in reducing that rate.

There was a large increase in the vote for housing. The position in that respect was improving, but although 8000 odd houses were built last year, that was still far below what was necessary for the needs of the people as a whole. But the numbers were going up, and for the first time they had touched and passed the figure of 1000 houses in a month. In May, 1175 houses were built and completed. In the case of rickets, although that disease was still very prevalent in the cities, there was a marked decline recorded by all the public health authorities, except those of Paisley. Rickets did not show that correlation with housing which one would expect; it was not specially associated with a poor standard of housing. It occurred among the better class of people as well as among the poorer artisan class. In considering Poor-law relief in Scotland, and the adequacy or inadequacy of the scales granted, as well as the tremendous weight of unemployment during the past few years, and the burden cast by the general strike and the coal stoppage, they had to remember that so far no irreparable damage had been done to the health of the people; the vital statistics were still moving favourably, and if they had sense they could continue to keep them moving in that direction.

Mr. STEPHEN, in moving to reduce the vote by £100, said with respect to the vital statistics they all knew that figures might prove anything. Because of the coal stoppage the Board of Health had felt it necessary to send a circular to the parish councils of Scotland, similar to that issued by the English Ministry of Health, indicating that it was more important to have regard to financial considerations than to the granting of adequate relief in cases of destitution. It was true that the circular drew attention to the necessity of adequate relief being given, but while they had to have that in view the Board said, "For Heaven's sake do not spend too much money in doing it." The circular suggested that there should be communal meals. The Glasgow parish council had taken the circular very much to heart, and had decided that relief should be given entirely in kind. There were over 1000 women and 2000 children dependents of miners who were being fed by the Glasgow parish council, and he protested strongly against the way in which the feeding was carried on. In his own division the infantile mortality figures were 164 per 1000. The Government, not content with murdering children, were evidently going to proceed now to murder the miners' wives who were unfortunate enough to live in that division.

### *The Question of Hospital Accommodation.*

Mr. STEWART asked the Government what their intentions were in regard to the report of the Committee appointed in June, 1924, and which reported in December, 1925. That Committee, which was presided over by Lord Mackenzie, considered the question of hospital accommodation in Scotland. The report pointed out that there were a large number of cases which required hospital accommodation, but that under present conditions they could not be treated. Very disastrous results followed all round. Many cases waited for months, sometimes as long as a year, and even longer. The lives of many of these patients might be saved if they had earlier treatment and earlier medical attention. The Committee estimated that there was a shortage of 3600 beds to meet the normal requirements of the people; 3000 of these beds were in general hospitals and 600 in connexion with maternity hospitals. No provision was made for patients suffering from certain infectious diseases. With regard to maternity cases, under the Notification of Births Act local authorities were made responsible where the people themselves were not in a position to provide the necessary medical and nursing attendance. Many of these births took place in one or two-roomed houses, and according to the medical evidence where complications ensued they were absolutely unsuitable for the carrying out of any operation. The Committee estimated that to meet these requirements at least 600 beds were necessary. They had heard that day from the Under-Secretary the tremendous advance which had been made in reducing deaths from tuberculosis, but at the same time he admitted that, so far as surgical tuberculosis was concerned, they were not progressing nearly so well. The Committee again drew attention to the fact that while Scotland, so far as sanatorium accommodation was concerned, was not on the whole badly served, more accommodation was required for the treatment of surgical tuberculosis in children. What was the Government doing in that direction? The Committee stated that, so far as the Poor-law hospitals were concerned, they were as well-equipped and as up to date as any general hospital throughout the country. But there was this difficulty that, because of the stigma attaching to the Poor-law in Scotland, the people would not use these hospitals and went to the infirmaries instead. He thought that steps should be taken as quickly as possible to divorce these hospitals from the Poor-law administration and to place them under the local authority in the same way as infectious diseases hospitals. While what he had said was true of Glasgow, it was not true generally of the whole country. The Committee condemned very roundly indeed the conditions obtaining in many of the so-called hospitals connected with the Poor-law. Nursing was bad, and proper medical attention could not be given. The accommodation was utterly insufficient and out of date, and the sanitary and hygienic arrangements were not what they should be. This was not the first time that the conditions of Poor-law hospitals had been brought to the attention of Parliament. In 1909, when the Royal Commission sat, the conditions in Scotland were condemned with regard to the standard of nursing in Poor-law hospitals. He hoped that the Government in the immediate future, where they had the power—and he thought they could act without further legislation—would force dilatory parish councils to take such action, either by themselves or in combination with other parish councils, as would afford a higher standard of treatment in these institutions than was at present being given. A large number of ailments were prevalent among school-children which required special medical attention and nursing. There were no hospitals under the control of the education authority to deal with these cases, and the Committee recommended that the local education authority should be made responsible, and that there should be a development towards providing beds for these children in hospitals over which the education authority would have some control.

He also wanted to draw attention to the conditions of the hospitals and medical service in the Highlands and Islands. There was a grant of £13,000 a year for medical services in the Highlands and Islands. But that sum was being more than taken up, and it was not sufficient to pay the medical officers for the extra attention which they were called upon to give, and there was nothing left to provide the hospitals which were required. The recommendation of the Committee was that, apart from Inverness, at least 100 beds ought to be provided forthwith. Successive Boards of Health for Scotland had shown some consideration for the improvement of the conditions under which the poorer people of the country lived, and this was now producing marked results, which would ultimately, in his opinion, pay for all the money spent in that direction. Good health meant everything; it meant intelligence and morality. If the body was physically diseased and not properly cared for they could not have that standard of life which was the ideal of everyone. He should like, therefore, to have an assurance from the Secretary for Scotland that he was alive to the necessity of the case, and that the Government would be prepared, even at some little cost, to take the necessary steps which would ultimately mean a still further development and improvement of health services in Scotland.

Mr. HARDIE also protested against the way in which the wives of miners and miners' children were being fed during the present stoppage in the mining industry in Scotland. He said that the Government had decided to put the most harrassing conditions possible on these people who applied for the scanty and rotten food which was supplied. Captain Elliot, who was a medical man, would understand the meaning of this. Dinner was at 4.30 P.M., and breakfast at 8 o'clock in the morning; a fast of 15 hours. The mothers, and particularly the pregnant ones, were harrassed by being brought out to the feeding centres twice a day.

### *Mental and Venereal Disease.*

Mr. SCRYMGEOUR urged that steps should be taken to provide additional accommodation at the institution for mentally defective children in Dundee. He would also like to know whether patients who had been treated in sanatoria for tuberculosis and had returned to their occupations had been subjected to a serious return of the malady which had necessitated their return to the sanatorium. As regarded the question of venereal disease, there had been in the municipalities an extension of the system of providing medical advice and treatment for cases which were voluntarily reported. Whether or not that step was bringing about all the good results which might have been expected from it they could not say, but it would be very helpful if they had some official information. The difficulties in the way of compulsory notification were considerable, but in view of the awful results of the disease not only to the patients themselves, but to succeeding generations, he thought there was a strong argument for compulsory notification. Some improvement was being effected in t treatment of mentally deficient adults, and those in charge of mental institutions were making arrangements to facilitate recovery by seeing that the patients were not brought too much in contact with one another. Specialists by constant study of a particular defect or weakness of the mind had produced wonderful results. He had given some attention to this matter, and although he admitted that improvements had been made in the conduct of these institutions, he was disappointed at the rate of progress. He was disappointed that they should still send to an institution a man who had been reported as liable to take the life of his wife, and had been duly certified. Although there was no further indication of any tendency of the kind, it was impossible to get a doctor to say that the man should be allowed out of the institution. He had found that the surroundings and the patients with whom he was brought in contact destroyed the slightest likelihood of any change for the better, and tended rather to make things go from bad to worse. By treatment in a private institution, where care, consideration, and study could be given to each patient's particular weakness, more substantial results could be obtained. Certainly this subject called for steps a long way in advance of those already taken.

Mr. Sullivan complained that the Government this year were reducing the amount for the treatment of tuberculosis by £5000, in spite of the fact that they knew that it took years of work to effect an improvement in dealing with this disease. They were beginning to turn back the hands of the clock in this important matter. They had also been very successful in dealing with venereal disease. If the good work was kept up they might be able to stamp out that disease, but he saw from the report that the amount of money for this purpose was reduced by £6000.

Captain Elliot said that that was only a nominal reduction of the money spent, and was due to more closely estimating the amount required. No actual reduction was being made.

Mr. Sullivan said he had too much experience to be put off with that sort of answer. The result of saving in 1926 would be that tuberculosis and venereal disease would increase, and more money would be required later. He also noticed that under the heading, "Medical Benefit—Grant in Aid," there was a decrease of £44,000. It was £229,000 in 1925. The authorities must have done pretty well if they could spare that amount. In this thing, which the Government called economy, they were interfering with the chance of life of the people they represented.

Mr. William Graham said he trusted that in any circular that the Government issued to the Scottish local authorities they and the authorities themselves would make it perfectly plain that these services in Scotland—services of public health and venereal disease, and certain other services—were comparatively new for the purposes of grant, and beyond all doubt in Scotland there was a vast field to overtake in respect to them; that the tendency of recent legislation had been to throw extra burdens on the local authorities, and that so far the principle of ability to pay was not so strict in local rating. All these things should be pressed in any representations from Scotland on this very important subject. He was very much afraid from an administrative point of view that the pass might be sold. If the Government decided upon some form of block or overhead grants it was perfectly plain that in Scotland that must mean, unless these services were to be curtailed, extra burdens for many local authorities. It was also perfectly clear that these burdens would fall with cruel weight on the poorer and more crowded and densely populated areas which were already carrying the tragedy of more than four years of industrial distress.

### *Scottish Secretary's Reply.*

Sir J. Gilmour (Secretary for Scotland), replying to the debate, said that with regard to hospital accommodation in Scotland he was aware that the Committee, presided over by Lord Mackenzie, had presented a report which was deserving of the very closest consideration. All he could say at the moment on the general problem was that the Board of Health were taking the matter into their closest scrutiny, and he hoped that they might be able in the course of time to provide an increased number of beds. This year they were making a grant to institutions in the Stornoway area to meet part of this problem. These grants only affected places where they hoped to do more, and they were quite alive to the necessity of doing all they could in that direction. With regard to sanatorium treatment of tuberculosis, and things connected with it, what they had done had not quite realised all the hopes they expected, but he thought he could say that they were making progress with that problem. Some progress was also being made in regard to the treatment of venereal disease. One of the most practical parts of the success of that treatment was that the individuals concerned must submit themselves to treatment if the fullest advantage was to be obtained. The remarks made on certain aspects of mental cases would also be carefully considered. He was not losing sight of the peculiar circumstances of Scotland and the more special claims she had upon the resources of the country in connexion with housing. As regards the points raised in the very interesting speech of Mr. W. Graham, he was sure that the right hon. gentleman would not expect him to make any declaration on a subject which was sub judice at the moment. Some hard things had been said about Poor-law relief. The duty of the Government was undoubtedly to give the parish councils guidance at a time like the present, and in accordance with that duty and in consultation with the Minister of Health these instructions had been issued. He did not think that they could be shown to be in any sense harsh or unfair, nor indeed when one came to consider how the parish councils throughout Scotland had faced the difficulties and responsibilities which had been thrown upon their shoulders, could one honestly say that they had been administered in a harsh or cruel or vindictive spirit. A great deal had been said about the hardship caused to women being unable to go long distances to attend the centres, but in such cases arrangements had been made for the food to be sent to their own homes.

The amendment and the original motion were withdrawn.

### *Pensioners and War Neurosis.*

Mr. Robert Young asked the Minister of Pensions what number of pensioners were receiving treatment for war neurosis and other shell-shock complaints; and whether the treatment given was wholly in Ministry of Pensions hospitals or otherwise.—Major G. C. Tryon replied: In April last there were some 3350 of these cases undergoing treatment. Of these cases, with the exception of 300 who are receiving treatment in their own homes, and 61 being treated in or at civil institutions medically approved by the Ministry, all the cases were being treated in hospitals or at clinics owned or under the medical control of the Ministry.

### *Whole-time Medical Officers of Health.*

Lieut.-Colonel Fremantle asked the Minister of Health if it was the policy of the Ministry to secure the replacement of general medical practitioners by specialist medical officers of health throughout the country as and when possible; what was the proportion of whole-time to part-time medical officers of health when this policy was originally adopted by the Local Government Board in 1872; and what was the proportion now.—Mr. Neville Chamberlain replied: It is the general practice of my department to approve, where possible, the appointment by local authorities of whole-time medical officers. As regards the remainder of the question, a Parliamentary return, published in 1873, shows that for England and Wales the proportion of whole-time appointments was about one-quarter. At the present time the proportion is slightly over one-third, the number of authorities having considerably increased.

### *General Practitioners and Preventive Medicine.*

Lieut.-Colonel Fremantle asked the Minister of Health if he proposed to utilise general medical practitioners for the prevention as well as cure of disease in the community in his reorganisation of the public health system and his proposals for reform of the Poor-law; and what steps he was taking to improve education in the medical curriculum accordingly.—Mr. Neville Chamberlain replied: In common with my predecessors, I have always been anxious that general practitioners should take their full share in preventive medicine, but the proposals for the reform of the Poor-law will not affect the responsibilities of general practitioners in this regard, and as at present advised I see no necessity to invite my noble friend the Lord President to advise the General Medical Council to consider any further modification of the medical curriculum with this object in view.

### *Optical Appliances for Insurance Patients.*

Sir Arthur Shirley Benn asked the Minister of Health whether he was aware that certain approved societies had made arrangements with the Joint Council of Qualified Opticians and the National Association of Opticians for the supply of spectacles to their members; and whether he would see that the free choice of an optician by members was not interfered with.—Mr. Neville Chamberlain replied: I am aware that some approved societies have made arrangements with organisations of opticians for regulating the quality and price of optical appliances to be supplied to members of the societies who are entitled to ophthalmic benefit as an additional benefit under the National Health Insurance scheme. Having regard to the fact that at present it is open to any person to supply spectacles to the public, although possessing no particular qualifications, I see no reason, as at present advised, to interfere with arrangements which are designed to protect the interests of insured persons by securing that articles of a satisfactory quality shall be obtained at a reasonable price

### *Maternity and Child Welfare Centres*

Mr JOHN PALIN asked the Minister of Health the number of maternity and child welfare centres in existence in England and Wales at the present time, and the figures at this time last year —Mr NEVILLE CHAMBERLAIN replied: On June 1st, 1926, there were 2403 maternity and child welfare centres known to my department in England and Wales, as compared with 2385 on the corresponding date last year

### *Imports of Condensed Skimmed Milk.*

Mr HURD asked the Minister of Agriculture how much condensed skimmed milk had been imported this year from countries where animal diseases were rife; what this volume represented in liquid milk; and how it compared with the imports from those countries for the corresponding period in 1925 and 1924 —Mr WALTER GUINNESS replied I am advised that the temperatures to which this condensed milk is subjected in factories on the continent are sufficient to destroy the virus of foot-and mouth disease and the tubercle bacillus. The imports of sweetened condensed skimmed milk from countries in which there has been a considerable amount of foot-and-mouth disease have been as follows:—

| | Cwts | Approximate equivalent in liquid milk (gallons). |
|---|---|---|
| January to May, 1926 | 734,132 | 24,065,000 |
| „ „ 1925 | 634 086 | 20,786 000 |
| „ „ 1924 | 569,377 | 18 065,000 |

The trade returns do not separately distinguish the imports of non-sweetened condensed skimmed milk. So far as I am aware, other animal diseases are not especially prevalent in countries from which imports of condensed milk are obtained

### *Expenditure on Medical Services in Kenya Colony*

Dr SHIELS asked the Secretary of State for the Colonies whether he had noted the recommendation made by the acting governor of Kenya Colony, in the report of his official tour through the provinces in 1922, that it would be both unwise and unjust to restrict Government expenditure for educational and medical services, on the ground that the people were taxing themselves for those purposes through their native councils, and whether he would state how far the principle thus recommended had been observed —Mr AMERY replied: Yes, Sir I have noted the recommendation, and while I cannot give a categorical reply to the last part of the question, I can assure the hon. Member that the expenditure on native educational and medical services is increasing

Dr SHIELS asked the Secretary of State for the Colonies what steps had been taken to meet the recommendations made by the Kenya Economic and Finance Committee, in its Interim Report on Native Labour in 1925, that steps should be taken to lessen the high death-rate amongst the natives by an increase of the medical services in the reserves. —Mr AMERY replied The total medical provision has been increased in the 1926 estimates from £131,031 to £178 961 Among the increases are 10 medical officers and two sanitary overseers for the native reserves, and six nurses, two male orderlies, and a large number of native attendants for native hospitals.

## FRIDAY, JUNE 18TH.

### *Cost of Domiciliary Poor-law Relief*

Mr WHITELEY asked the Minister of Health whether he could state the total remuneration of relieving officers and other officers employed in connexion with domiciliary relief, excepting medical officers, dispensers, and other persons employed in the treatment and care of the sick for the years 1923–24, 1924–25, and 1925–26 —Mr N CHAMBERLAIN replied: The total remuneration (salaries, rations, &c., and superannuation allowances) of relieving officers and other officers employed in connexion with domiciliary Poor-law relief in England and Wales, excepting medical officers, dispensers, and other persons employed in the treatment and care of the sick, was £1,017,709 during the year 1924–25 and £981 000 during the year 1923–24 The figures for the year 1925–26 are not yet available.

### *Maintenance and Treatment of the Insane*

Mr WHITELEY asked the Minister of Health the amount of expenditure on the maintenance of lunatics in lunatic asylums during the years 1924–25 and 1925–26.—Mr N CHAMBERLAIN replied: For the financial year 1924–25 the amount of expenditure on the maintenance, supervision, and treatment of the insane in county and borough mental hospitals in England and Wales was £9,510,639 This amount does not include any expenditure in respect of loan charges, repairs, additions, and alterations of buildings, or purchase or rental of land and buildings. Particulars are not yet available for 1925–26

### *Bodies Removed to Medical Schools*

Mr WHITELEY asked the Minister of Health the number of bodies removed to medical schools in England and Wales for the purpose of anatomical examination and operative surgery during the years 1924 and 1925 —Mr N. CHAMBERLAIN replied: The number of bodies removed to medical schools in England and Wales for the purpose of anatomical examination and operative surgery was 510 during the year 1924 and 581 during the year 1925

### *Remuneration of Poor-law Medical Staff*

Mr WHITELEY asked the Minister of Health the approximate remuneration of Poor-law medical officers, dispensers, and nurses during the years 1923–24, 1924–25, and 1925–26 —Mr N CHAMBERLAIN replied: The money payments to Poor-law medical officers, dispensers nurses, and other officers employed in the treatment or care of the sick in England and Wales amounted to £1,500,021 during the year 1923–24, and £1,553,000 during the year 1924–25 The figures for the year 1925–26 are not yet available.

## MONDAY, JUNE 21ST

### *Royal Asylums and Income-tax.*

The House went into Committee on the Finance Bill, Mr J F HOPE in the chair

Sir R. HUTCHISON moved the following new clause providing that (1) exemption shall be granted (*a*) from income-tax under Schedule A in respect of lands, tenements, hereditaments, and heritages owned and occupied by a royal asylum for lunatics and mental patients, not being such lands, tenements hereditaments, or heritages as are mentioned in No. VI. of Schedule A; (*b*) from income-tax under Schedule B in respect of lands occupied by a royal asylum for lunatics and mental patients, (*c*) from income-tax under Schedule D in respect of any profits derived by a royal asylum for lunatics and mental patients. (2) The exemption granted by paragraphs (*a*) and (*b*) of Subsection (1) of this section shall not extend to tax in respect of any rent payable or other annual payment to be made by a royal asylum for lunatics and mental patients in respect of lands, tenements, hereditaments, or heritages which are in the use and enjoyment of a person whose total annual income from all sources, estimated in accordance with the provisions of the Income-tax Acts, amounts to not less than £150 (3) Exemption shall not be granted under this section to a royal asylum if the receipts from private patients are in excess of the receipts from pauper patients. He said that these royal asylums in Scotland had been subscribed to by the public. They were run for no profit and the funds had been administered by individuals who had given their time for no remuneration. These asylums had in many cases saved the parish council large capital expenditure in that they accepted at a very low rate, and catered for, patients sent to them by those parishes. In later years the work of those asylums had been added to by a large number of cases from the parish councils so that these asylums were not only doing the charitable work which they were originally intended to do, but they were also doing a public work in taking those patients from the various parish councils. Any surplus which their funds might show at the end of a year was devoted entirely to reducing the rates which were charged to the various patients, as well as to the maintenance of the buildings and to generally developing these very good institutions. There were also one or two smaller institutions —they were not really royal hospitals, but district asylums —which to-day were exempt from the very tax from which he was trying to induce the Chancellor of the Exchequer to exempt these royal asylums At the present moment these district asylums were only exempt under Schedule D and it seemed very hard that these royal asylums should not be so treated. Under a royal charter in 1913 they were given the duty of looking after the patients coming from public authorities, and for that reason he thought they were entitled to be exempt from many of the items on which they were now assessed. They took patients who otherwise would cost a very large sum of money, and, further than that, they subscribed towards paying part of what otherwise would be charged to poor patients, to the necessitous mental cases who were sent there and could not afford to pay the nominal rate Those cases were taken by the royal asylums at a special low rate, below the actual cost This showed that these asylums were within the category of charitable institutions He thought that the chief reason why some of them were at present charged income-tax was because they accepted private patients. They undoubtedly accepted private patients, but the whole of the profit that came from those private patients went towards reducing the rates charged to other people, and helped the unfortunate patients who could not pay any fees at all. It also assisted in reducing the rate charged to the parish councils. Further than that, farms were also run in connexion with these institutions, and these farms had produced a surplus, but the farms were part of the cure of the mental cases, and they also produced the food required by these royal asylums. The general administration of these institutions came well within the definition of a "hospital" within the meaning of the Act.

Mr. Churchill said that he regretted that he was not in a position to accept the proposal, much as he would like to do so. He readily admitted the many substantial arguments which had been adduced in support of the new clause, but at the present time they gave a very wide exemption to charity, much wider than the Royal Commission on Income-tax had recommended. They gave, in fact, an immense exemption, which cost the revenue over £10,000,000 a year. The question arose as to where they were going to draw the line and he found great difficulty in widening the scope of the exemptions now granted to charities. In order to restrict those exemptions within some bounds which would not make very serious inroads on the revenue, certain conditions had been insisted on. They were not the conditions which the Royal Commission thought ought to be insisted on, but they were the only bulwark which the revenue had against an altogether indefinite variety of arguments for the extension of these exemptions. The courts had laid down that in the case of a hospital or charity exemption only applied to institutions maintained to a great extent by charitable endowments or subscriptions. It was not sufficient to say that they were not working for a profit, but they must be maintained to a great extent by charitable endowment. There were several of these royal asylums in Scotland, but there were only two of them which escaped these provisions—Montrose and Aberdeen. He thought for the sake of meeting the difficulties of these two hospitals, it would be a very serious thing for them to throw over the whole of the existing basis of the exemptions from income-tax. His hon. friend had spoken about the district asylums, but they differed from these two royal asylums, in that they depended to a substantial extent on money from charitable sources. He was afraid in all these circumstances it was impossible for him to meet the proposal of his hon. friend. The whole question of charitable relief, notwithstanding the somewhat adverse recommendation of the Royal Commission, might well be a subject of future reflection. There was no doubt that even trying to draw the lines where they had to be drawn—and some lines must be drawn—a number of hard cases, borderland cases, must arise. If at any time it was possible to take a more liberal view of those borderland cases, that ought to be done, not on a variety of special institutions such as had been mentioned that day, but as a result of a comprehensive and general consideration of the question and of a successful attempt to lay down more harmonious limiting principles which would prevent indefinite exemptions from the law.

The clause was negatived without a division.

### *Benefits to Nursing Mothers.*

Sir Charles Wilson asked the Minister of Health if he would consider favourably an extension of benefits to nursing mothers from one to three months.—Mr. N. Chamberlain replied: Under the National Health Insurance Act an insured married woman is entitled to receive, in addition to the maternity benefit payable in respect of her husband's insurance, a second maternity benefit on condition that she abstains from work for a period of one month after her confinement, but thereafter no further benefit is payable unless she is incapable of work. As a result of the second valuation of approved societies the average rate of maternity benefit has been increased from 40*s.* to 46*s.*, and consequently the total amount which the woman will receive will be £4 12*s.* on the average. I understand the suggestion of my hon. friend to be that this period of one month should be extended to three months, with a corresponding increase in the amount of the benefit, where a woman abstains from work in order to suckle her infant. This would impose a considerable further burden on insurance funds, and I do not see my way to introduce the necessary amending legislation, particularly as no such proposal is included in the recommendations of the recent Royal Commission on National Health Insurance.

### *Births and Deaths Registration Bill.*

The Births and Deaths Registration Bill, as amended in Standing Committee, was considered on report.

Mr. Basil Peto moved the following new clause: (1) The death of any person shall not be registered unless and until there has been delivered to the registrar of the district in which such death has occurred a certificate, signed by a medical practitioner, of the fact of death and of the cause of death, as respectively in this Act defined, and such certificate shall be given only after he has inspected the body. (2) It shall be the duty of the General Medical Council to establish a fund by equal annual contributions from all persons on the Register who are actually practising, from which such fee as they may decide shall be paid to every medical practitioner for each inspection and certificate. He said that one would have thought that in a Bill of this kind the very first consideration would be that the registrar should have definite proof by medical evidence that a person in regard to whose death he was required to grant a certificate was in fact dead. But in this Bill there was no condition whatever that any medical officer who viewed a body should certify that the person was actually dead. Under Clause 7, which dealt with the registration of still-births, there was a provision that the body of a still-born infant should be inspected by a medical man. In the larger question the same should apply. In previous Bills there had been an attempt to insert such a provision, but the question had always been as to who should pay. The local authorities did not want to be burdened. The medical profession took the view that it was in the interests of somebody else and not in the interests of the medical profession, and therefore clearly somebody else should pay. That was a view with which he had a certain sympathy, and he thought that he had arrived at a method by which to cut the Gordian knot by recognising exceptional cases. He thought that in 99 cases out of 100 the fee for the inspection of a body under this Bill would not be disputed by anybody, and would be paid as a matter of course. There were, however, cases of medical practitioners with large practices who visited a very great number of poor people in crowded centres, like the East End of London, where they would have to make a good number of inspections during the year, and where in a considerable number of cases it might be very difficult or impossible for those who came after the deceased to pay more than the absolutely necessary expenses. It was a very small thing to ask the whole body of medical practitioners to form a sort of pool. By a quite minute contribution from each of them annually they could form a fund from which poorer practitioners, who had most of these inspections to make, could draw a reasonable fee as recompense for their loss of time. There was also the case of doctors practising in sparsely populated rural districts, where a single inspection might involve a good deal of time and expense.

Mr. Groves seconded the proposed new clause.

Captain Elliot (Parliamentary Under-Secretary for Health, Scotland) said this was a Bill which had been prepared and gone into with very great care, and had passed through all its stages so far after a careful examination by a Standing Committee of the House. It was supported by members of all parties. It would not be possible for the Government to accept this clause, and if it was passed the result would be to wreck the Bill and bring to naught all the work which had been put into it both in the House and outside.

The clause was still under discussion when, under the rules of the House, the debate was adjourned.

## TUESDAY, JUNE 22ND.

### *Waterproof Sandpaper in Painting Industry.*

Lord Henry Cavendish-Bentinck asked the Secretary of State for the Home Department how many master painters had caused waterproof sandpaper to be employed in rubbing down; how many were still using it; and whether he had any information as to their views on its practical value as a substitute for dry rubbing down in the painting of houses, interior and exterior.—Captain Hacking replied: I regret I am unable to furnish the precise information asked for in the first part of this question, but the inquiries my right hon. friend has made indicate that the new process has not been adopted yet to any great extent. As regards the last part, I would draw the attention of the noble lord to the letter which appeared in the *Times* on the 10th inst. from the secretary of the Painting Trade Materials Committee of Great Britain and Ireland, in which he states that a considerable number of painting trade firms have found a new process both satisfactory as a preventive of lead dust and economical in cost. I understand that this has been the general experience of firms carrying out painting work for the Office of Works which, as the noble lord will be aware, prohibits the use of dry rubbing down in all its painting specifications.

### *Milk and Dairies Order.*

Colonel Day asked the Minister of Health, in view of the urgency of the matter, when he proposed to issue the proposed new Order in connexion with the supply of milk.—Mr. N. Chamberlain replied: I regret that I cannot give any precise date for the issue of the Milk and Dairies Order, but I hope to be able to make the Order very shortly.

# Medical News.

UNIVERSITY OF GLASGOW.—The Graduation ceremony took place on June 23rd. Prof. Archibald Young delivered an oration on Sir William Macewen, busts of whom were presented to the University and to Lady Macewen. The following degrees were conferred in the Faculty of Medicine:—

*M.D.*—With honours: John K. Rennie and George M. Wishart. With commendation: Walter P. Grieve. Ordinary degree: William K. Anderson, James S. Bissett, and David Robertson.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful:—

FINAL EXAMINATION FOR DEGREES OF M.B., CH.B.

*Part I., including Forensic Medicine and Toxicology*.—Edward C. Bernard, Juan M. Camps-Campins, Alfred J. McD. Grimston, and Thomas M. White.

*Part I. only*.—Douglas E. C. Andrew and Hubert E. C. Bentley.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION.—The council will hold its next meeting in Prague on August 20th. Following the business there will be meetings and social functions to which any medical women will be welcome. The agenda of the open meetings include discussions on (1) tuberculosis and pregnancy, (2) women police surgeons. It is hoped that some members of the Medical Women's Federation of Great Britain will include Prague in their holiday itinerary. Further particulars may be obtained from the Secretary of the Association, Miss M. I. Robertson, 28, Weymouth-street, London, W. 1.

HARVEIAN SOCIETY OF LONDON.—The annual dinner of the Harveian Society was held at the Connaught Rooms, London, on Thursday, June 17th, when the President, Mr. Laming Evans, took the chair at a well-attended gathering of members and their guests. The toast of "The Harveian Society" was proposed by Sir Archibald Garrod, who congratulated the Society on its ancient foundation and its present prosperity, and was responded to by the President. Mr. Laming Evans, after alluding to the ups and downs of the Society during a history of 95 years, pointed out that membership appealed to general practitioners, consultants, and specialists, the net of the subjects chosen for discussion being widespread. He was glad to say that the attendances at the meetings had recently considerably increased, and concluded by announcing the institution of the Buxton Brown Prize Essay, consisting of a medal together with a sum of £50 to be awarded biennially. The essays, he said, "would be adjudicated upon by two assessors, who would receive a handsome honorarium, and by the President who would receive none." The subject of the first competition he announced as "The Ætiology of High Blood Pressure and of the Respiratory Phenomena associated with it and with Chronic Nephritis," an apt choice of subject in a Society named after William Harvey, for the great master, though living to 70 years of age, was a martyr to gout and high blood pressure—circumstances which Mr. Laming Evans guessed "might be associated with the perquisites of office as physician-in-ordinary to Charles I., one of which was a diet of three dishes of meat a meal with all incidents thereunto belonging."

The toast of "The Guests" was proposed by Dr. Walter Jagger, who, in a humorous speech, referred to the representative nature of the guests and invited the most prominent of them, the Secretary of State for War, to explain the deductive and inductive reasons for the Christian name which he shared with his brother, their President. Sir Laming Worthington-Evans thanked the Society for its hospitality, and pointed out that he would leave the questions of induction and deduction to other speakers who were to reply to the toast. Sir John Rose Bradford reminded the audience that Harvey considered material refreshment a very fitting accompaniment to scientific discussion, but added that owing to depreciation in values Harvey's actual bequest to the Royal College of Physicians of London for the purpose of feasting was now represented by the purchase of a bag of macaroons. Sir Oscar Warburg, chairman of the London County Council, who also replied to the toast, closed the evening with an encouraging message as to the wonderful effect that medical effort had produced in our vital statistics.

The guests included, in addition to the speakers, Sir Richard Glazebrook, Sir John Lithiby, Sir Frederick Butler, Sir StClair Thomson, Sir Holburt Waring, the Mayor of Paddington, the Master of the Society of Apothecaries (Dr. Vincent Dickinson), the President of the Hunterian Society (Mr. A. E. Mortimer Woolf), the West London Medico-Chirurgical Society (Mr. H. W. Armstead), the Chelsea Clinical Society (Dr. Seymour Price), Sir Squire Sprigge, and Dr. Charles Buttar.

PEOPLE'S LEAGUE OF HEALTH.—The general meeting will take place at the Mansion House on Monday, July 5th, at 4.30 P.M., the Lord Mayor of London presiding. The speakers will include Dr. E. Farquhar Buzzard and Prof. Edgar L. Collis.

UNIVERSITY OF LEEDS.—Dr. R. D. Passey, lecturer in pathology at the Welsh National School of Medicine, has been appointed to the new chair of Experimental Pathology and to be Director of Cancer Research and Mr. Bryan Austin McSwiney to the chair of Physiology (from Manchester).

CHURCH MISSIONARY SOCIETY: *Medical Mission Auxiliary*.—The annual meeting will be held in the Central Hall, Westminster, at 7.30 P.M. on June 29th. The chair will be taken by Major-Gen. Sir Richard H. Luce, and the speakers will be Rev. H. T. Marrable, M.B., B.Ch. Dub., late of Persia, Dr. E. Villiers Hunter, of Uganda, and Dr. C. Vosper, of Srinagar, Kashmir. Tickets for admission can be obtained on application to the Loan Department of the Society, Salisbury-square, London, E.C. 4.

THE LATE DR. W. O. JONES.—The death took place on June 16th of William Owen Jones, of the Downs, Altrincham, the oldest and one of the best known medical men in North Cheshire. He was a student at the Manchester Medical School and at St. Mary's Hospital, and qualified M.R.C.S. in 1861. After qualification he acted as senior house surgeon and resident medical officer at the Manchester Royal Infirmary. A native of Bala, Merionethshire, he settled in Bowdon, Altrincham, where he practised for more than 60 years, retiring from practice two years ago. He was in his eighty-sixth year.

UNIVERSITY OF OXFORD: *Radcliffe Prize*.—The next award for this prize will be in the year 1927. The prize, which is of the value of £50, is awarded by the Master and Fellows of University College every second year for research in any branch of medical science. It is open to all graduates of the University who have proceeded, or are proceeding, to a medical degree in the University. Candidates must not have exceeded 12 years from the date of passing the last examination for the degree of Bachelor of Arts, and must not, at the date of application, be Fellows on the Foundation of Dr. John Radcliffe. Candidates must send in their memoirs to the Secretary of Faculties, at the University Registry, on or before Dec. 1st, 1926.

BRUSSELS UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—At the annual meeting of the Association, held at 147, Harley-street on June 9th, it was decided to change the name of the Association to "The Brussels University Medical Graduates' Association." The annual dinner will take place in October, when new members will be welcomed. Particulars of the new medal of the Association, either in gold or silver gilt and enamel, may be obtained from the hon. secretaries. The following officers were elected:—President: Dr. Fielden Briggs. Vice-President: Sir Thomas Carey Evans, M.C. Council: Dr. Robert Wilkinson, Dr. Arthur Cowburn, Dr. Eustace Callender, Dr. Edward Smallwood, Sir Bruce Bruce-Porter, Dr. Bryce Macaulay, Dr. R. W. Brimacombe, Dr. Russell Corfield, Dr. Mainwaring Hughes, Dr. Langford Campbell, O.B.E. Hon. Treasurer: Dr. James Metcalfe. Hon. Secretaries: Dr. Arthur Haydon, Dr. A. D. Woolf.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Mr. Doyne will give a clinical demonstration in ophthalmology for the Fellowship of Medicine on Thursday, July 1st, at 12 noon, at the Royal London Ophthalmic Hospital (Moorfields), City-road, E.C. This demonstration is open to the medical profession without fee. The Prince of Wales's General Hospital will hold a vacation course from July 19th to July 31st, occupying the whole of each day. The course will consist of clinical and laboratory methods, demonstration of groups of selected cases, general hospital work, and clinical lectures dealing with various subjects. From July 5th to July 17th the National Hospital for Diseases of the Heart gives an intensive course, and between the same dates the Hospital for Diseases of the Skin, Blackfriars, holds an afternoon course. The West End Hospital for Nervous Diseases will begin a four weeks' late afternoon course comprising lectures and clinical demonstrations upon selected cases at the out-patient department, 73, Welbeck-street, W. From July 12th to July 24th the Royal Eye Hospital will start a series of demonstrations on eye diseases from 3 P.M. daily. During August the following courses will take place: In medicine, surgery, and the specialties at Queen Mary's Hospital (Stratford); diseases of the chest, Brompton Hospital; and diseases of children, Queen's Hospital, Hackney. All of these courses will be all-day ones. Copies of all syllabuses, of the General Course [illegible] copies of the *Post-Graduate Medical Journal* may [illegible] application to the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

The annual dinner of past and present students of St. Mary's Hospital Medical School will be held at the Connaught Rooms, Great Queen-street, London, W.C., on Monday, Oct. 4th, at 7 for 7.30 P.M.

Royal National Hospital for Consumption, Ventnor.—The medical report for last year shows the clinical results as improvement in 64·7 per cent. of cases, "no change or worse" in 33·4 per cent., and deaths in 1·9 per cent. Of the early cases 93 per cent. improved; of the intermediate ones 80 per cent.; in the advanced cases, representing 72·7 per cent. of the total, the percentage of improvement was 51·7.

Extension of the Hartlepools Hospital.—The new "Morison Wing" of this hospital is to be opened by Princess Mary in August. The accommodation will be increased from about 60 to 90 beds, and the Red Cross Society and the Order of St. John have contributed £5000 towards the cost. There will be male and female medical wards, a children's ward, and accommodation for the whole of the nursing staff.

St. Thomas's Hospital Medical School.—The distribution of prizes took place on June 22nd, Sir Arthur Stanley, treasurer of the hospital, presiding. Sir Cuthbert Wallace, dean of the medical school, spoke of the athletic as well as the academic successes of the year. This year six cups had been won. The Bristowe medal and the Mead medal were won by Mr. R. B. Alston, who had since died of septic poisoning. Sir John Bland-Sutton distributed the prizes. He recalled the inspiring history and traditions of the hospital and congratulated the authorities on the wise policy that welcomed those trained elsewhere to positions on the staff if it seemed desirable.

International Congress for Life-saving and First-aid to the Injured.—The third international congress will be held in Amsterdam from Sept. 7th to 11th. A British section has been formed under the presidency of the Duke of York to arrange for the representation of this country at the congress, and it is hoped that a large number of members will attend. It is proposed to form a party to travel from England, and reduced fares will be available. A provisional programme of the congress has been issued. Lectures, discussions, and international competitions in life-saving and first-aid will be held, and various societies interested, such as the St. John Ambulance Association and the National Fire Brigades Association, will send teams to compete. Full details can be obtained on application to the General Secretary, Miss M. A. Harvey, at 7, Cambridge-street, Hyde Park, London, W. 2.

The late Rev. Dr. Henry Charles Packard.—The Rev. Dr. Packard, who died recently at Kedleston, of which place he was rector, was born in East Anglia in 1856 and was educated at Trinity College, Dublin, where he graduated in arts in 1885, in medicine and surgery in 1895, and proceeded to the M.D. degree in 1897. From 1882 to 1885 he was curate at Walthamstow and in the following year held a similar position at Homerton. Two years later he went to China as a missionary, where he was engaged in hospital construction and in furthering the crusade against leprosy. In 1898 he was again in this country as curate of St. Matthew's, Ealing Common, and later became priest and tutor to the Wadhurst Hall Mission in East London. For two years he was chaplain and physician to Hanwell County Asylum and in 1924 received the living of Kedleston. Dr. Packard was a man of lovable disposition, who took for his watchwords kindness, toleration, and forgiveness. He leaves a widow and four sons.

The late Dr. Horatio W. A. Cowan.—The death of Dr. H. W. A. Cowan occurred with tragic suddenness on May 28th in his house at Fitzroy-square. Dr. Cowan was born at Inverness 52 years ago. He received his medical education at Aberdeen University and St. Bartholomew's Hospital, London. He qualified M.B., C.M. Aberd. in 1895, taking the M.D. degree in 1909. After qualification he came to London, and for two years was assistant to a general practitioner. While so occupied he managed to find time to hold clinical appointments at the Throat Hospital, Golden-square, Moorfields, and the Hospital for Consumption, Brompton. Subsequently, he visited Australia and New Zealand as surgeon on a White Star liner, and afterwards entered the Royal Navy. He resigned in 1900 to settle in practice in Fitzroy-square, where he continued until his death. He built up a large practice and was deservedly popular, for he was a hard worker, a most sympathetic doctor, and in every way up to date, reading largely professional subjects and giving much anxious thought and care to his patients. He was beloved by all, and his untimely end is a source of sorrow to the whole neighbourhood. His interests, besides professional, were varied and included yachting and motoring. He leaves a widow, one daughter, and a son who succeeds him in the practice.

The Office Français du Tourisme informs us that, contrary to rumours which have appeared in the press, no Government restrictions affecting the convenience of foreign tourists or limiting the consumption of petrol are to be anticipated.

The New Westminster Ophthalmic Hospital. The removal (and consequent enlargement) of this hospital from Charing Cross to the new freehold site in Broad-street, W.C., will involve the expenditure of at least £50,000 beyond the available resources and the Duke of Connaught, the President, is supporting an appeal for that amount.

Research Defence Society.—The annual general meeting will be held at the House of the Medical Society of London, 11, Chandos-street, Cavendish-square, W. 1, to-day (Friday), June 25th, at 3 o'clock, Lord Lamington, the President, in the chair. An address will be given by Dr. J. A. Murray, F.R.S., Director of the Imperial Cancer Research Fund, on the Experimental Attack on Cancer. The report contains the formal expression of deep regret at the death of the founder of the Society, Mr. Stephen Paget. The audited accounts for the year ending Dec. 31st, 1925, show a marked improvement in the financial position of the Society in response to much vigorous work.

Rockefeller Medical Fellowships.—The Medical Research Council announce that on behalf of the Rockefeller Foundation they have made the following awards of Medical Fellowships provided by the Foundation and tenable in the United States of America during the academic year 1926–27: Geoffrey Bourne, M.D. Lond., M.R.C.P., first assistant in the Medical Unit, St. Bartholomew's Hospital, London; Hugh William Bell Cairns, M.B. Adelaide, F.R.C.S., assistant surgeon, London Hospital; Miss Rosalie Evelyn Lucas, M.B. Bristol, clinical assistant, Maudsley Hospital, London; Ronald Douglas Mackenzie, M.B. Edin., M.R.C.P. Edin., lecturer in pathology, University of Edinburgh; Carl Frederick Abel Pantin, M.A. Camb., assistant physiologist, Marine Biological Laboratory, Plymouth; Arthur Frederick Bernard Shaw, M.D. Trin. Coll. Dub., F.R.C.P.I., lecturer in pathology, University of Durham; James Calvert Spence, M.D. Durh., M.R.C.P., medical registrar and chemical pathologist, Royal Victoria Infirmary, Newcastle-on-Tyne; Harry Ellis Charter Wilson, M.B. Glasg., assistant in chemical physiology, University of Glasgow. Dr. Lucas and Mr. Pantin have been appointed on modified conditions while holding scholarships or emoluments from other sources.

Royal Sanitary Institute.—At the Congress to be held in London on July 5th to 10th, the Minister of Health presiding, the jubilee of the Institute will be celebrated. Over 1000 delegates have been appointed to attend, representing Government departments, foreign Governments, and Overseas Dominions. The proceedings will be held in six sections, with presidents named below: (*a*) Sanitary Science and Preventive Medicine, Sir George Newman; (*b*) Engineering and Architecture, Sir Charles T. Ruthen; (*c*) School Hygiene, Lord Eustace Percy; (*d*) Personal and Domestic Hygiene, Councillor Ellen C. Wilkinson, M.P.; (*e*) Hygiene of Food, Sir William Hardy, F.R.S.; (*f*) Hygiene in Industry, Alderman Sir Charles Wakefield. Seven conferences will be held:—(1) Representatives of Sanitary Authorities. President: The Lord Mayor of London (Sir W. Pryke). (2) Representatives of Port Sanitary Authorities. President: Mr. Victor Brown. (3) Medical Officers of Health President: Dr. G. F. Buchan. (4) Engineers and Surveyors. President: Mr. G. W. Humphreys. (5) Veterinary Inspectors. President: Alderman W. Phené Neal. (6) Sanitary Inspectors. President: Sir William J. Collins. (7) Health Visitors. President: Mrs. Hilton Philipson, M.P. Joint Session with the Conference on Maternity and Child Welfare. President: Lady Forster of Lepe. Among the subjects to be discussed are preventive medicine from various aspects, rheumatism and its results, the relation between sanitation and parasitic infections in the tropics, new streets and buildings by-laws, concrete houses, recommendations made to the Board of Education Advisory Committee with reference to the introduction of physiology into schools, progress in the dairy industry, factory medical service, biological treatment of sewage, and the Public Health Acts—a plea for consolidation. On July 5th, at 3 P.M., the inaugural address to the congress will be delivered in the Guildhall by Mr. Neville Chamberlain. On July 7th, at 8 P.M., Prof. C. E. A. Winslow, of Yale University, will give an address on Appraisement of Health Administration, at the Institute. The dinner in celebration of the jubilee of the Institute will be held in the Hotel Cecil on July 8th, at 7.30 P.M., Mr. Neville Chamberlain in the chair. Further particulars of the social and other functions to be held in connexion with the Congress may be obtained from the Secretary at the Institute, 90, Buckingham Palace-road, London, S.W. 1.

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W

THURSDAY, July 1st.—5 P.M., Annual General Meeting of Fellows.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W

MONDAY, June 28th, to SATURDAY, July 3rd.—Special demonstration in clinical ophthalmology by Mr Doyne on Thursday at 12 noon at the Royal London Ophthalmic Hospital, City road, E.C This demonstration is open to all members of the medical profession, without fee —ALL SAINTS HOSPITAL, Vauxhall Bridge-road, S.W Special Course in Urology Clinical and Cystoscopic Demonstrations on Monday and Wednesday afternoons and evenings. Thursday and Saturday afternoons. Special lecture at 2 P.M., June 30th by Mr J C Ainsworth Davis, "Renal Tuberculosis." Further information from the Secretary, Fellowship of Medicine

NORTH EAST LONDON POST GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham N

MONDAY, June 28th —10 A.M. Surgical Out patients Mr W E. Tanner 10 30 A.M., Gynæcological Operations Mr A. E. Giles Throat, Nose, and Ear Operations Mr W. Ibbotson, 2 P.M., Medical Surgical, and Gynæcological Clinics Operations. *6 30 P.M., Venereal Department*

TUESDAY —2 P.M., Medical, Surgical Throat, Nose and Ear Clinics, Operations 3 P.M., Demonstration of cases Illustrating Types of Mental Diseases Dr J E. C Laing at the Colney Hatch Mental Hospital New *Southgate, N*

WEDNESDAY —10 30 A.M. Surgical Operations Mr E. Gillespie 2 P.M., Medical, Eye, and Skin Clinics, Operations. 6 30 P.M., Venereal Department.

THURSDAY, July 1st.—10 30 A.M., Dental Out patients Mr E. S Pierrepont 2 P.M., *Medical, Surgical and* Throat, Nose and Ear Clinics, Operations. 5 P.M., Operations.

FRIDAY —10 30 A.M., Eye Operations Mr N Fleming 2 P.M., Surgical, Medical, and Children Clinics. Operations. 3 P.M., Dr G E. *Sundell Cases of Children's* Disease in the Wards. 6 30 P.M., Venereal Department.

CANCER HOSPITAL, Fulham road S.W

WEDNESDAY, June 30th.—4.30 P.M., Mr C E. Shattock Malignant Disease of the Tongue.

FRIDAY, July 2nd —4.30 P.M., Dr R. Knox: Recent Developments in Diagnosis of Gall Bladder Lesions

LONDON SCHOOL OF DERMATOLOGY, ST JOHN'S HOSPITAL, Leicester-square, W C.

TUESDAY, June 29th.—5 P.M., Dr A. C. Roxburgh Warts

THURSDAY —5 P.M., Dr S. E. Dore: Mycosis Fungoides.

# Appointments.

BANKS, H S., M.B., Ch.B. Glasg. *D P H.*, has been appointed Superintendent of Leicester City Hospital and Isolation Sanatorium.

DUFF, D, F R.C.S. Edin., F R.F.P.S Glasg., Visiting Surgeon, Glasgow Royal Infirmary Lecturer and Examiner in Clinical Surgery, University of Glasgow

LEVI, DAVID, M.S. Lond., F R.C.S. Eng., Surgical Registrar to St. Mary's Hospital.

MCGIBBON, R. T., M.B, Ch.B Glasg., Professor of Anatomy, University of Saskatchewan, Saskatoon, Sask., Canada

PARKER, W, M.B., Ch.B Edin., D.P.H., County Medical Officer for Worcester.

PASSEY, RICHARD DOUGLAS, M.D, B S Lond., to the new chair of Experimental Pathology and Director of Cancer Research in the University of Leeds.

ROBINSON, J S, M.B, B Ch. Dub F R.C.S Edin., Honorary Surgeon and Orthopædic Surgeon, Cheltenham General and Eye Hospitals.

SULLIVAN J., M B., Ch.B Edin., D.P H., Medical Officer of Health for Fulham.

WILLIAMSON, BRUCE, M.D Edin., M.R.C.P Lond., Hon. Physician in charge of the Out Patients Department at the Royal Northern Hospital, Holloway

Salford Royal Hospital: CHANCE, O., M.B., Ch.B. Dub., and ECCLESTON, C, M.B., Ch.B Manch., House Surgeons. BROADHURST, W, M.B., Ch.B Manch., Casualty *House* Surgeon.

# Vacancies.

*Royal Free Hospital, Gray's Inn-road, W C* —Cas. O £150

*St Paul's Hospital for Skin and Genito-Urinary Diseases, Endell street, W C* —H.S. £200

*Scarborough Hospital and Dispensary* —Two H S.'s. At rate of £125

*Sheffield Royal Hospital.*—Vacancies on Resident Medical and Surgical Staff. At rate of £80

*Sheffield Royal Infirmary* —Two H.S.'s., H.P., Asst. Cas. O. and Ophth. H.S. All at rate of £80

*University of London.—External Examiners*

*West London Hospital, Hammersmith-road, W* —Res. Asst S. £200

The Chief Inspector of Factories, Home Office, Whitehall, S.W, announces the following vacant appointments for Certifying Factory Surgeons Berwick (Northumberland), Sunderland, Neilston (Renfrewshire)

The Secretary of State for the Home Department gives notice of vacancies for Medical Referees under the Workmen's Compensation Act for the Districts of the Pocklington and Selby County Courts (Circuit No. 15) and the Beverley, Bridlington, Goole, Great Driffield, Howden, and Kingston-upon-Hull County Courts (Circuit No. 10), and the Districts of the Consett, Durham Seaham Harbour, and Sunderland County Courts (Circuit No 2).

# Births, Marriages, and Deaths.

## BIRTHS.

COOKE.—On June 19th, at Herne House, Petersfield, Hants, the wife of Dr R. Campbell Cooke, of a daughter

COYTE.—On June 14th, at Harley-street, the wife of R. Coyte, F R.C.S., of a daughter

REA.—On June 15th, at Harley-street, the wife of R. Lindsay Rea, F R.C.S., of a daughter

SAWDAY —On June 15th the wife of A. Ernest Sawday, M B., B.S. Lond., of Hartington-street, Derby, of a son.

STEPHENS.—On June 15th, at Terrace Houses, Richmond Hill to Celia Mary Colquhoun Macnell, M.B., Ch.B., wife of Cromwell A. Stephens—a son.

TUCKER.—On June 18th to Ena Mildred Tucker, M.R.C.S., L.R.C.P., the wife of Robert L. Tucker, of Compayne-gardens, Hampstead—a son.

## MARRIAGES.

DAVIDSON—BALMER.—On June 17th, at Eccles Congregational Church, Alexander Whyte Davidson, M.C., M B., F R.C.S.E., to Elizabeth Thubron, third daughter of Arnold W Balmer, Esq, Barrister-at Law, and Mrs. Balmer, of Eccles, Lancs

## DEATHS.

TURTLE.—On June 14th suddenly, at Peckham Rye, S E., Frederick Wenman Turtle, M.D, aged 61

*N.B —A fee of 7s 6d is charged for the insertion of Notices Births, Marriages and Deaths.*

# Notes, Comments, and Abstracts.

## THE TEACHING OF CONTRACEPTIVE METHODS AT WELFARE CENTRES.

IN the debate in the House of Lords on April 28th upon the attitude of welfare centres to artificial birth control several points of medical interest were raised. The motion was as follows: "That his Majesty's Government be requested to withdraw all instructions given to, or conditions imposed upon, welfare committees for the purpose of causing such committees to withhold information from married women in their district, when sought by such women, as to the best means of limiting their families." Into general questions raised in the debate, such as the relation between over-population and wars, the decline of the white races, under-population in France, the differential birth-rate in this country, &c., it would be irrelevant to enter here. Since, however, the motion was carried by 57 votes to 44, the strictly medical issues involved deserve scrutiny. Of these there were three, two occurring in the speech of the Archbishop of Canterbury and one in that of Viscount Fitzalan of Derwent.

According to the Archbishop of Canterbury's interpretation of the motion, there would follow from its enactment an intolerable compulsion on the officers in charge of welfare centres. There would be placed upon them the obligation to give information on contraception, even against their better judgment, if ever and whenever that information were asked for by a patient. "The medical man or woman," said the Archbishop, "needs to be protected against having that novel obligation laid upon him or her to give advice on the subject of contraception, which he or she might not wish to give." From these words the Archbishop would seem to envisage the possibility of doctors being legally compelled to give contraceptive information to women for whom there was no medical indication for such knowledge—women proposing to undertake a life of prostitution, for instance. It is, of course, highly unlikely that Lord Buckmaster ever contemplated anything of the sort. The criticism might well have been avoided if a clause such as, "at the discretion of the medical officer," or "if the applicant be considered on medical grounds to require such information," had been incorporated in the motion. It is important that if the matter be further discussed in the House of Commons, the doctor's liberty of action be safeguarded by some such clause.

The second point of medical interest raised by the Archbishop of Canterbury was that the Ministry of Health did not expect, indeed did not wish, its regulations on the matter of welfare centres and birth control to be acted upon too strictly. The regulation in question runs as follows: "It is not the function of an antenatal centre to give advice in regard to birth control, and exceptional cases, where the avoidance of pregnancy seems desirable on medical grounds, should be referred for particular advice to a private practitioner or hospital." The Archbishop then said that in order to satisfy himself as to whether the Ministry of Health intended this regulation to be taken literally he had made inquiries of "the highest authorities" of the Ministry, of whose replies he had made a memorandum. The memorandum need not be reproduced in full. Two short excerpts will be sufficient to illustrate the point: "In all cases attending the clinics where information is necessary on medical grounds, advice is always given by the doctor irrespective of any request on the part of the mother"; and, "The extreme medical cases in which another birth would be likely to prove disastrous for the mother are few and far between. Such cases would not ordinarily attend a maternity or infant welfare centre, but, if and when they did, it may be safely assumed that the mother would be advised as to the right course to adopt in order not to have any more children." It is clear that the attitude of these "highest authorities" of the Ministry of Health interviewed by the Archbishop is not consistent with the regulation by which medical officers of welfare centres are supposed to be bound. The Archbishop is justified in his view that the regulation is not expressed in the happiest phraseology, and if the Ministry of Health could see its way to revising the wording of this regulation, a source of considerable and not ill-grounded misunderstanding would be removed.

Viscount Fitzalan raised a point of closer medical interest by reciting a list of names of distinguished medical men and women who are opposed to artificial birth control. The grounds upon which this opposition is based seem to resolve themselves into four—that contraceptives are useless in preventing conception, that they produce local disease, that they cause sterility, and that their use is followed by various psychoneuroses. It is to be noted, however, that medical men and women who work in birth control clinics claim that when women desiring information on contraception receive the skilled supervision (whether from qualified medical women or from trained midwives) which is made available at these clinics, few, if any, of them suffer from the above complications. This fact suggests the possibility that some persons, who, on the grounds of its medical harmfulness, are opposed to artificial birth control, may fail to distinguish between the injury following the promiscuous use of pessaries, bought through advertisements or from shops, which are adjusted without proper medical advice or supervision, and the harm that results from their use when properly fitted by a competent person after the pelvic examination and inspection of the cervix has been properly performed. This, we understand, is the routine at the clinics. This distinction is an extremely important one to establish before the technique of contraception, or, indeed, any technique is condemned on medical grounds. It would be hardly logical or fair to use as an argument in favour of not extending wide medical supervision to the use of contraceptives, the fact that the absence of such supervision has in the past proved disastrous. Statistical evidence on the question is clearly required. At present the only sources of adequate statistical information as to the harmfulness or otherwise of the use of pessaries when properly fitted seem to be the various birth control clinics under medical charge. It would therefore be both profitable and relevant if the Ministry of Health were to institute an impartial investigation into the statistics now in possession of these various clinics. From such an inquiry there might emerge results which justify the attitude of those who were quoted by Viscount Fitzalan as opposing artificial birth control on medical grounds; on the other hand, the results might well be such as to convert an argument against contraception which the prestige of its celebrated opponents has invested with importance, into a compelling argument in favour of that extension of the existing medical supervision of birth control which is demanded by Lord Buckmaster in his motion.

There has recently been published a pamphlet on the management of a birth control centre,[1] written by a lay worker with four years' experience as superintendent of the Walworth Women's Welfare Centre. In this pamphlet stress is rightly laid on the importance of proper professional direction in the matter of instructing poor mothers in means of birth control. The importance of such supervision is emphasised in view of the enormous trade now done by unscrupulous firms and shops which specialise in the sale of contraceptive devices, usually at extravagant prices. Of the harmfulness of this trade there can be no shadow of doubt. The pamphlet is clearly written, and contains no birth control propaganda. It is issued with the sole object of providing practical assistance to those who agree with the methods and objects of a Society for the provision of birth control clinics, and who wish to create other centres like the few—there are only six in London and the provinces—now administered by this Society.

## COLONIAL HEALTH REPORTS.

### *British Guiana.*

ACCORDING to the report for 1924 prepared by Mr. B. H. Bayley, Second Assistant Colonial Secretary, the population on Dec. 31st was estimated as 301,204—157,772 males and 148,132 females. The birth-rate for the year was 32·4 per 1000 of the population distributed as follows among the several races representing the community: Europeans other than Portuguese, 14·1; Portuguese, 23·9; East Indians, 34·5; Chinese 27·5; Aborigines, 34·3; blacks 29·9; mixed races, 37·4. Of the births registered 54·8 per cent. were illegitimate. The aggregate death-rate was 25·6 per 1000, or, taking the various races, among Europeans other than Portuguese, 13·1; Portuguese, 29·8; East Indians, 27·7; Chinese, 20·7; Aborigines, 30·3; blacks, 24·7; mixed races, 20·2. The number of children who died under 1 year of age was 1606, or 165 per 1000. The general health of the colony was good, and there were no epidemics during the year. The climate of the colony (which it is interesting to note is the only British possession on the South American continent), although warm, is distinctly cooler than that of other British colonies in tropical latitudes, and Europeans and other northern races enjoy consistently good health. The mean temperature throughout 1924 was 80·5° F. The heat, which is greatly tempered by cooling breezes from the sea, is felt most from July to October owing to decreased force of these breezes. There are annually two wet seasons, from April to the middle of August and during December and January The rainfall in 1924 was 83 51 inches, as compared with an average over the past 44 years of 91 9 inches.

---

[1] On the Management of a Birth Control Centre. By Evelyn Fuller. With an Introduction by the Hon. Miss Graham Murray, O.B.E. The Weardale Press: 26, Gordon-street, W.C.1. 1s.

### *St. Lucia.*

In his report on the affairs of the colony for 1924 Mr G D Mackie, Acting Administrator, states that the estimated population at the end of December was 51,304. The birth rate (excluding stillbirths) was 35·7 per 1000 of the total population and the death rate (excluding stillbirths) 21 4 per 1000 The infant mortality rate was 132 5 per 1000, the primary cause of death being intestinal diseases due to worms and improper feeding. The year was a comparatively healthy one, no epidemic having occurred. The principal causes of death, in order of frequency, were; intestinal parasites, 116, senile decay, 96; malaria, 86 tuberculosis, 75, pneumonia, 61; syphilis, 55; infant debility, 31. The intensive treatment of hookworm disease was continued by the Rockefeller International Health Board during the year The following hospital accommodation is provided: Victoria Hospital, 116 beds; Soufrière Casualty Hospital, 8 beds Vieux Fort Casualty Hospital, 8 beds, Dennery Casualty Hospital, 7 beds; Pauper Asylum (for infirm and incurable patients), 98 beds; Leper Asylum 30 beds; *Lunatic Asylum, 100 beds. St. Lucia,* which is situated at a distance of 24 miles to the south-east of Martinique and 21 to the north-east of St. Vincent, is 24 miles in length and 12 at its greatest breadth; its circumference is 150 miles and its area 233 29 square miles rather less than Middlesex. The port of Castries is one of the best harbours in the West Indies. The town of next importance is Soufrière Just below Soufrière Bay stand the remarkable twin peaks known as "The Pitons," rising sheer from the sea to a height of 2619 feet in the case of the Gros Piton and 2461 feet in that of the Petit Piton. The boiling sulphur springs from which Soufrière gets its name are situate at Ventine, 2½ miles south-east of that town The climate is healthy Temperature varies between 70° F, in the cool season, from December to May, to 90° in the remainder of the year The rainfall at Castries for the year was 82 88 inches—2 25 inches above the average for 25 years A comfortable hotel has been established, and by judicious advertising there is no reason why the colony should not become a winter resort for visitors from Europe and North America.

### *Trinidad and Tobago.*

Mr T A. V Best, C.M.G, Colonial Secretary, in his report for 1924, gives the estimated population of the two islands on Dec. 31st as 381,753 The white population is chiefly composed of English, French, Spanish, and Portuguese. The large majority of the inhabitants are natives of the West Indies of African descent, the balance being made up of East Indians, estimated at 123,903 and a small number of Chinese. The birth-rate for the year was 33·66 per 1000 and the death rate 20·02 per 1000 The infantile mortality rate was 124 07 per 1000 births. The death rates from the principal diseases were diarrhœa and enteritis, 1 38 per 1000; malaria, 1 90; tuberculosis, 1 26; dysentery, 0·60; enteric fever, 0 55; ankylostomiasis, 0 82 The year was a very healthy one, the birth rate being high and the death-rate and infantile mortality reaching a low record for the colony Venereal clinics on modern lines continue to be well attended at Port of Spain and San Fernando. On the recommendation of the central board of health, drainage schemes for the control of malaria are being continued in the country districts, and minor measures of a similar nature were maintained. The *intensive* treatment of hookworm disease was continued by the Rockefeller International Board of Health. The central board of health coöperated by enforcing the establishment of latrines in advance of the treatment in the areas about to be operated in. The following hospital accommodation is provided: Colonial Hospital, Port of Spain, 340 beds; the San Fernando Hospital 123 beds; the Government district hospitals at Tobago, and at Arima St Joseph Tacarigua, Couva, Princes Town, and Cedros 248 beds. There are also small temporary hospitals at Sangre Grande, Mayaro and Toco. The climate is healthy and by no means hurtful to Europeans, provided reasonable precautions are taken. The average temperature during the day is 84° and during the night 74° F The average rainfall in 1924, from records taken at 110 stations, was 60·42 inches.

---

## HARRISON'S "POPULAR MEDICAL ERRORS"

AMONG the pioneers of labour legislation the name of James Bower Harrison M D F R C.S., of *Broughton* Manchester, deserves honourable mention. Descended through his father, the Rev William Harrison from a long line of preachers who dated back to the days of *the Restoration*, he was himself in the best sense a moral reformer By a paper in the *Dublin Medical Quarterly* and a letter, addressed to Lord Shaftesbury, on the expediency of submitting certain trades and manufactories to medical inspection, he was largely instrumental in leading to a Government inquiry into the conditions of child labour in unhealthy occupations. The result of this inquiry was the Act of 1847 restricting the hours of women and young persons to about ten a day But Harrison was not only a social reformer, he laboured assiduously in such leisure as he could snatch from the routine of a large practice, surgical and general, to disseminate rational views of medical matters among laymen. His publication 'Popular Medical Errors' published in 1851 after appearance as a series of articles in *Chambers's Journal*, had a great vogue. Merely to copy the headings is to obtain a curious bird's-eye view of what domestic medicine consisted in the early Victorian era and what superstitions Harrison proposed to scotch. Though quite a number of the old fallacies are still matters of popular belief, especially in nurseries, but frequently among hospital out-patients, yet there is a mellow completeness in the ancient body of error which the present is without. Thus some 80 years ago the following things were so commonly believed as to make it worth Harrison's while to deal with them: That lunatics are influenced by the moon, that cooling medicines should be taken at particular periods of the year, that hair can turn gray in a night, that a sound rather than a poor constitution is compatible with severe chronic disease, that proud flesh ' filled up wounds that corns have roots as do trees, that hydrophobic patients bite those around them and should be smothered by the doctor, that a loud voice is a proof of strong lungs, that the alcoholic are liable to spontaneous combustion, that milk produces phlegm in coughs that every seven years there is a change in the constitution, that most skin troubles are "scurvy,' that scarlet fever shades off into scarlatina, that blood removed by the application of leeches is 'as black as your hat," that leeches placed on the eyelids weaken the sight that "cinder tea' is good for children, that the 'ninth day" of a confinement is very important, that a man may put out his neck and a skilful friend in the hunting field may at once put it in,' that the eyes can be taken out and replaced by ophthalmologists, that acute boils and gouty attacks are healthy, that there are drawing salves and strengthening" plasters, that 'mothers marks' are photographs of ideas held by mothers during the prenatal period that bones are brittle in winter that *red* flannel is a sovran remedy, that poison resides in the heart of the mussel which should be removed, that "galvanic' rings cure rheumatism and fits that "a narrow swallow" may prevent the taking of pills, that babies suffer from inward fits" and that medical men know some secret trick by which they avoid contagion.

It should be noted that it was not only the ignorant and uneducated who held these beliefs and passed them down till they became traditional wisdom, but educated men in the absence a century ago of any general scientific training held devoutly to the truth of some of these comical ideas. The smothering of a hydrophobic is described in one of Blackmore's novels as a lurid but logical incident, and both Dickens and Marryat employed spontaneous combustion to remove disagreeable persons. Dr Harrison's enumeration of popular medical errors of which the above is only a long quotation contains delightful colloquial illustrations showing him to be a man of humour as well as shrewd observation The book was written while he was quite a young man and preceded a great deal of popular writing on the medical aspects of industrial and social conditions. It is probable that he owed his access to many lay journals to his cousin Harrison Ainsworth also a Manchester man who, in addition to being a popular novelist, was associated as editor or regular contributor with many newspapers and magazines.

## THE MEDICINAL VALUE OF WILD HERBS.

THE use of many of our wild plants as articles of food as well as for their medicinal value has nowadays almost completely disappeared with the establishment of the potato as a staple article of diet and the replacement of the itinerant herbalist by the patent medicine vendor Such wild and apparently useless plants as the chickweed or the nettle have, however a definite food value, and Mrs. M Grieve, in a recent little book[1] on wild vegetables, salads and their vitamin value discusses many neglected varieties giving frequent delightful quotations as to the medicinal value of the plants she describes Thus the wild cabbage, which grows freely on the cliffs at Dover, was regarded by Pliny as the most esteemed of all vegetables, and he recommended its use in 87 remedies. A decoction of yellow goat's beard was stated by Nicholas Culpeper, who wrote a famous book on herbs in the seventeenth century, to be "good for heart-burn, loss of appetite, disorders of the breast and liver." The same authority claimed great medicinal powers for various preparations of the leaves of succory or wild chicory. "The distilled water of the herb and flowers . . . . is good for swooning and passions of the heart." Lovage, an umbelliferous plant growing on the rocky coasts of Scotland, "helps the quinsey" and "removes spots and freckles from the face," says Culpeper. The scurvy grass growing on muddy sea-shores has some historic interest, for "scurvy-grass ale" was used by Captain Cook as an antiscorbutic in one of his voyages in the South Seas. The use of garlic as a household remedy is not altogether forgotten even at the present day, and the seed of the hedge garlic, known popularly as Jack-by-the-hedge, has been recommended for "poisons and venom and worms in children." Watercress, as has recently been pointed out by Dr. H. Scurfield, contains all three vitamins and should be eaten more than it is. Culpeper states that the juice of this plant mixed with vinegar is good for "the dull and drowsy." Shepherd's-purse made into a poultice was used by the same authority for "St. Anthony's fire." The leaves of the marsh mallow were stated by Tyron in his "Way to Health," published in 1683, to "cure near fifty diseases." The nettle is still gathered each spring by country dwellers and a tincture made from this plant has been recommended for various skin eruptions. Pepys relates having good nettle porridge placed before him as a guest. Perhaps some of these neglected medicinal plants may receive consideration at the hands of the committee now engaged in revising the British Pharmacopœia.

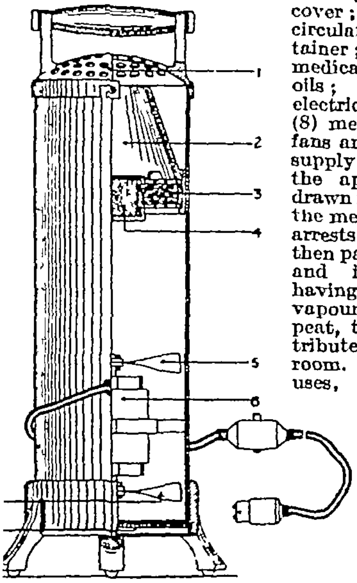
## THE "DEODOS" AIR CLEANSER.

THE purpose of this apparatus is to purify and medicate the air of rooms and buildings by means of a vapour. The parts of the apparatus shown in the illustration are: (1) detachable perforated cover; (2) air-diverting cone; (3) circular perforated charcoal container; (4) central vessel for medicated peat and fumigating oils; (5) delivery fan; (6) electric motor; (7) suction fan; (8) medicated filter screen. The fans are worked from the electric supply of the building in which the apparatus is used. Air is drawn into the "Deodos" through the medicated filter screen, which arrests all solid impurities; it then passes over prepared charcoal and is deodorised. Finally, having been charged with the vapours of specially medicated peat, the perforated cover redistributes this new air into the room. In addition to its medical uses, which should be under the advice of a medical man, the "Deodos" may prove useful in clearing the internal atmosphere of tobacco smoke, odours of cooking, new paint, and so forth, as well as in perfuming an apartment. The manufacturers are the International Deodoriser Syndicate, 69, Basinghall-street, London, E.C. 2.



## ESERINE IN GLAUCOMA.

*To the Editor of* THE LANCET.

SIR,—Cases treated in the course of work for the Blind Relief Association here confirm the value of eserine in the treatment of glaucoma.

A. B., woman, aged 45; glaucoma, practically no vision Treated in camp with eserine 1 gr. to ounce, pupils contracted, and after the third day was able to see the tent.

C. D., man, aged 30. Right eye destroyed; on left eye, glaucoma, little more than perception of light. After one treatment vision greatly improved, but field remained much contracted. Later brought to the Civil Hospital, where eserine was continued with field greatly improved.

Two cases with glaucoma, no sight. Both recovered sight after eserine six times a day. *One seen again after a year, sight quite good.* This case had not even P.L. originally.

Generally here the instillation of eserine is made two or three times a day in a strength of 4 gr. to ounce. The results indicate that it is a most valuable drug which should be given a good trial before operation. In one case at least where an operation was done first and eserine instilled afterwards no improvement took place.

I am, Sir, yours faithfully,

B. C. VACHHRAJANI, L.M. & S., B.M.S.,

Medical Officer, Thar Parkar Civil Hospital, Mirpurkhas, Sind, India; Chairman, Blind Relief Association.

May 1st, 1926.

*** The value of eserine in glaucoma is well recognised in this country. In some incipient cases it may be all the treatment required, in some chronic cases it may succeed in arresting the progress of the disease for months or even years, and in all acute or subacute cases it is of great use as one of the measures calculated to put the eye into the best possible condition for operation. On the other hand, it is now generally held that in the great majority of cases in which the diagnosis of glaucoma has been established, by far the best means to arrest a disease whose inevitable tendency is to advance to blindness is operative treatment, and that although eserine may be invaluable in some cases in which for any reason operation is out of the question, the latter is the only treatment which holds out a reasonable prospect of avoiding ultimate blindness.—ED. L.

## BRITISH SPAS.

*To the Editor of* THE LANCET.

SIR,—A rumour appears to have arisen to the effect that some of the British spas have been compelled to close down owing to coal shortage. As hon. secretary to the British Spas Federation I have communicated with all the resorts in the Federation and find that sufficient coal-supplies are everywhere available, and that every one of the British spas is giving full service to its visitors, and has every intention of continuing to do so.

The British spas have lately had to meet quite enough difficulties through foreign competition, adverse trade conditions and railway restrictions, without having to suffer the injury of baseless rumours. At Bath and Buxton, Cheltenham and Droitwich, Harrogate, Leamington and Llandrindod Wells, Strathpeffer and Woodhall Spa conditions are perfectly normal. Baths and treatments and entertainments are going on just as usual, and at the present moment thousands of people are finding health and enjoyment at the British spas.

I am, Sir, yours faithfully,

JOHN HATTON,

The Hot Springs, Bath, June 19th, 1926. Hon. Secretary.

## "ARDENTE-ACOUSTIQUE" ELECTRICAL AIDS FOR THE DEAF.

MR. R. H. Dent (95, Wigmore-street, London, W.) has submitted for our inspection some improved forms of his well-known apparatus for use by the deaf, constructed on the ordinary telephone principle. The first is a new small ear-piece, the size of a shilling, and said to be the smallest yet made; it is simple, light, and easily fits into the ear and does away with the use of lorgnettes, head-bands, and so forth. The second piece of apparatus is a small microphone about the size of a florin which can be used for general conversation or in a large room or hall. It is so constructed that it gathers sounds reaching it from wide angles, and is more powerful than the old box types. A special auditorium type of microphone is designed to collect sounds from any part of a church or public hall in a remarkably clear and true-to-tone manner. Another new novelty made by this firm is a small battery case of special material constructed to keep out damp and prolong the life of the battery. A feature of the "Ardente-Acoustique" aid for the deaf is that they are remarkably free from "buzz" or metallic timbre. The instruments are made in a variety of forms, and each is adapted to the needs of each particular case.

## SURGICAL FOOT-GEAR.

A West End branch of Scholl's Foot Comfort Service has been opened at 93, Regent-street, with the object of working in coöperation with the medical profession. An expertly trained staff will attend daily to carry out under medical instruction the fitting of the firm's arch supports and other corrective appliances. Thus in prescribing for foot ailments medical men will have at their disposal an organised service to render assistance in the carrying out of their instructions.

---

DONATIONS AND BEQUESTS.—Mrs. Eliza Mary Eccles, of Preston, besides other large bequests, gave £1000 each to the Preston and County of Lancaster Royal Infirmary to endow a "John Christopher Eccles" bed, and the United Kingdom Beneficent Association; £500 each to the Royal Cross Deaf and Dumb School, Preston, and the Preston Institute for the Blind.
